Looking Back to Look Forward: Highlights From 2020

Paclitaxel-Coated Devices: Update on Late-Mortality Signal

ACC, Merck Empowering Next Generation of Clinical Researchers

January 2021 Vol. 50 No. 1

| Call For Papers: Amyloidosis

Have your amyloidosis research featured in an upcoming special issue of JACC: CardioOncology. The deadline for submissions is April 15 to submit your papers for a special focus issue on amyloidosis being published in JACC: CardioOncology.

Original research submissions spanning the theme will be considered, including those examining epidemiology, diagnosis and prognosis, clinical management, phenotyping, pathophysiology, emerging therapies, comorbidities, the role of imaging and biomarkers and other relevant issues.

Scan the QR code to learn more.

Are You Ready to Join Cardio-Oncology Leaders at **Virtual Meeting?**

Plan now for Feb. 6, 2021 - and join live sessions from the Advancing the Cardiovascular Care of the Oncology Patient Virtual meeting.

Join Course Directors Ana Barac, MD, PhD, FACC, and Bonnie Ky, MD, MSCE, FACC, and the cardio-oncology community, for live education sessions with real-time discussion with faculty and case and poster presentations providing best practices and emerging strategies to advance patient care in your practice.

Scan the QR code to learn more about CME credit, view the full schedule and access special on-demand sessions available as early as Jan. 25.

New MR Education Now Available on ACC.org

A new education initiative available on ACC.org addresses knowledge gaps in the assessment and management of mitral regurgitation (MR), equipping cardiovascular professionals on the front line.

The Understanding and Managing MR: Evolving Science and Policy initiative, created by the ACC, provides the knowledge to assess patients with MR to determine etiology, mechanism and severity to guide timely and optimal intervention strategies.

Can you correctly distinguish primary vs. secondary MR? Take a new patient case quiz to find out. What are the five key elements of a comprehensive MR echocardiogram - listen and learn through a new ACC CardiaCast podcast episode.

Get more of the latest MR education, including lectures and expert panel discussions, in the Understanding and **Managing MR: Evolving** Science and Policy Hub.

TAVR For One! But TAVR For All?

nterventional cardiology is now more than 15 years into the use of TAVR, ever since **G. Alain Cribier**, **MD**, performed the first case in April 2002. The devices are now pretty slick, and so-called second- and third-generation devices have appeared. Paravalvular leaks are now less of an issue. Some enthusiasts are simply saying that TAVR is now "for all."

The appeal of TAVR is clear. The procedure is quick, hospitalizations in straightforward cases are short, general anesthesia is not necessary, use of hospital resources is less, patients are up and about feeling better in less time, and so forth. As a result, the use of TAVR is expanding to lower (and lower) risk and younger (and younger) patients.

Is it time to hit the "pause" button and reflect? In surveying the TAVR landscape, there are important issues still to be answered. Here are a few of them.

What did the randomized TAVR trials really tell us? PARTNER IB and the CoreValve Extreme Risk trials are no-brainers. TAVR was a clear winner over paired patients having medical therapy. But after those first trials, it gets a bit more complicated.

For patients at high risk (PARTNER IA, CoreValve High Risk) and intermediate risk (PARTNER 2A, PARTNER 2 S3i, SURTAVI) outcomes showed that TAVR and SAVR had equal outcomes.

In low-risk patients (PARTNER 3, CoreValve EVOLUT R), TAVR was noninferior to SAVR for the primary outcome of death, stroke and repeat hospitalization; in fact, TAVR showed superiority on additional analysis. What drove the differences? Mostly repeat hospitalizations in both trials. Death between SAVR and TAVR was not statistically significant in both trials, which was perhaps expected given the low risk of the patients. Stroke was low (at roughly <3% for both SAVR and So, can we really conclude that TAVR is for all? Not so fast!

Before sending that 50-year old patient with aortic stenosis to the cath lab for her/his TAVR, consider these questions.

What age groups were actually studied in these trials? The mean age was approximately 73 years in both! Can these data be applied to patients 20 years

or so younger? In PARTNER 3, only 7% of patients were <65 years. In EVOLUTE R only 6% were <65 years and 1.3% were <60 years.

What about pacemaker need? At one month, the Evolute R trial reported approximately 17% vs. 6% pacemaker use for TAVR and SAVR respectively. PARTNER

3 reported 6.5% vs. 4%, respectively. Meddling with the conduction system just below the aortic annulus has its price, but surgery still has the edge.

What about coexisting coronary disease? The exclusion criterion for extensive coronary disease in PARTNER 3 was a Syntax Score >32, and in EvolutR >22. Simply saying that higher degrees of coronary disease can be treated with concomitant/ additional stenting has to be called into question – especially now that we have longer term follow-up of the Syntax trials that show better surgical bypass results in complex disease.

Where do we stand on the pesky bicuspid valve question? Most younger patients with aortic stenosis have bicuspid valves. Data are sparse and no randomized trials of TAVR vs. SAVR have been done. The self-expanding CoreValve was studied in such patients and the results presented at ACC.20/WCC.

> The overall number was small (the study prospectively tracked 150 patients). On average, patients were 70 years old and had a Society of Thoracic Surgeons risk score of 1.4%. At 30 days, 1.3% of patients had died or experienced a disabling stroke. Of patients with a Sievers type 0 valve, roughly 15% had mild paravalvular leak after the

procedure. That amount of leak in a 50-year-old might not be a good thing over the next 30 years. Also, remember that many patients with congenital bicuspid valves also have associated proximal aortopathy. Interventionalists are eyeing that target for transcatheter therapy, but for now that is surgical territory.

What about valve size? If the annulus is too large or too small, a perfect transcatheter valve fit may be difficult. For small annular sizes, patient/prosthesis mismatch is a real issue. Especially for younger patients the hemodynamics of persistent outflow tract obstruction are long term issues. SAVR surgeons are not immune to producing patient/prosthesis mismatch. In the CoreValve High Risk trial, severe patient/prosthesis mismatch occurred in approximately 21% of patients. But, if needed and possible, SAVR surgeons can enlarge the aortic annulus and outflow; TAVR cannot.

A frank patient-physician discussion, or better a patient-heart team discussion **is still an important part of the equation for all involved** to outline the risk-benefit ratio of TAVR vs. SAVR for many.

> Bioprosthetic valves will, sooner or later, deteriorate. TAVR-in-TAVR can be performed, but at what risk? Data from the TRANSIT trial presented at TCT Connect 2020 indicate that in 172 patients from multiple international centers, the mortality at one year was 10%, with a cardiovascular mortality of about 6%. Many such patients have few other options, but surgery can be performed in some. Perhaps the option of a mechanical prosthesis originally placed would have been a better option in young patients despite the long-term anticoagulation issue.

Finally, there are absolute contraindications to TAVR: endocarditis, pure aortic regurgitation in a valve that might be surgically reparable, severe left ventricular outflow tract calcification, surgical "other valve" considerations, etc.

TAVR is a great alternative to SAVR in lots of patients – especially the elderly and those with morbidities that directly affect surgical risk. However, there are still many unanswered issues about which we have limited data. Should we accept that TAVR is for all? Not yet! For many patients facing aortic valve replacement, it is still imperative that we confront what we know and what we do not know. A frank patient-physician discussion, or better a patientheart team discussion is still an important part of the equation for all involved to outline the risk-benefit ratio of TAVR vs. SAVR for many.

Editor's Note: Turn to page 14 for a feature on TAVR and page 34 to learn about the new ACC/AHA Guideline on Valvular Heart Disease.

Peter C. Block, MD, FACC, is a professor of medicine and cardiology at Emory University Hospital and School of Medicine in Atlanta, GA. He thanks **Michael J. Reardon, MD, FACC,** for a summary of many of these data.

Is it time to hit the "pause" button and reflect? In surveying the TAVR landscape, there are important issues still to be answered.

TAVR) but just favored TAVR statistically (embolic protection devices were not allowed in the trials).

The PARTNER 3 trial, based on these findings, concluded that TAVR through one year *should be* considered preferred therapy in low-risk patients, while the EVOLUT R conclusions were slightly more conservative: TAVR *may be* preferred strategy to surgery in low-risk patients. Importantly, 10-year follow-up is planned for both trials.

ACC Joining Forces With BioIntelliSense Around Remote Cardiac Care

he ACC and BioIntelliSense, Inc., a continuous health monitoring and clinical intelligence company, have formed a strategic collaboration that combines innovative medical-grade wearable devices and data science to advance remote patient monitoring programs for cardiac care. The ACC will also offer the BioButton COVID-19 Screening Solution to provide an added layer of safety at ACC.21 in Atlanta in May.

The FDA-cleared BioSticker and medical-grade BioButton wearable devices allow for continuous vital sign monitoring of temperature, heart rate and respiratory rate at rest to enable early detection of adverse vital sign trends through its proprietary biosensor technology and advanced analytics. The strategic collaboration will combine ACC's clinical expertise in heart health with BioIntelliSense's effortless user experience and multi-parameter monitoring to make remote cardiac care scalable, reliable and cost effective.

"The ACC – and the cardiovascular community as a whole – has a long history of advancing innovative solutions to transform cardiovascular care and patient outcomes," says ACC President **Athena Poppas, MD**, FACC. "We are excited by the opportunity to partner with BioIntelliSense and be on the cutting edge of an innovative technology

We are proud to form a strategic collaboration with the American College of Cardiology to advance virtual care and remote patient monitoring (RPM) programs that can transform cardiac care. of an innovative technology with real-time health data and feedback."

Look for the BioButton at ACC.21 as part of ongoing efforts to create a healthy and safe environment for attendees, exhibitors and staff in line with all current directives and recommendations. In addition to all CDC recommended COVID-19 safety protocols, ACC.21 conference attendees will have the option to participate in the BioButton COVID-19 Screening Solution

COVID-19 Scre

James Mault, MD

for continuous vital sign and symptom monitoring for COVID-like infection. ACC.21 is the first major medical conference to use the BioButton solution.

"We are proud to form a strategic collaboration with the American College of Cardiology to advance virtual care and remote patient monitoring (RPM) programs that can transform cardiac care," says BioIntelliSense CEO **James Mault, MD**. "Together with the ACC, we can provide the cardiology community with medical-grade monitoring devices, clinically validated algorithms and RPM education that will have a profound impact on routine patient care globally. The inclusion of BioButton COVID-19 Screening Program to the safety measures for the ACC Scientific Session will also serve to provide [attendees] an opportunity to experience the simplicity of virtual care and effortless remote monitoring."

Look for the BioButton at ACC.21 as part of ongoing efforts to create a healthy and safe environment for attendees, exhibitors and staff in line with all current directives and recommendations.

ACC Names Jian'an Wang Inaugural Editor-in-Chief of JACC: Asia

ian'an Wang, MD, PhD, FACC, has been named the inaugural editor-of-chief of JACC: Asia, the ACC's first region-specific, open access cardiovascular journal with original peer-reviewed content. The Journal will publish original manuscripts and clinical practice guidelines specific to East Asian populations and by Asian authors.

Wang is a physician scientist who serves as the chair of the Heart Center at the Second Affiliated Hospital at Zhejiang University School of Medicine in China. He is also a professor and associate dean at Zhejiang University School of Medicine.

A leading interventional cardiologist, Wang has spearheaded the efforts in establishing and developing one of the largest valvular heart disease programs in Asia and has also developed several innovative devices for valvular interventions, in collaboration with engineers, cardiovascular colleagues and manufacturers, that have been approved by the China Food and Drug Administration. His research work focuses on improving the efficacy of stem cell implantation in infarcted myocardium through hypoxemic preconditioning, which has been validated on rodent model, non-human primate model and phase-1 clinical studies.

"It is a great honor and privilege to serve as the first editorin-chief of *JACC*: *Asia*," Wang says. "Our editorial team is excited to gather and publish the important scientific cardiovascular research coming from China, Japan and South Korea to help improve cardiovascular care and save lives. We look forward to working closely with cardiovascular research authors in the region and the *JACC* team

to achieve these efforts."

The first issue of JACC: Asia will publish early this year, with a call for papers happening soon. Learn more at JACC.org. Our editorial team is excited to gather and publish the important scientific cardiovascular research coming from China, Japan and South Korea to help improve cardiovascular care and save lives.

Jian'an Wang, MD, PhD, FACC

New TRANSFORM: ACS Program Aims to Optimize ACS Care

he ACC, in collaboration with Amgen and Veradigm, have announced a new national study to transform care for acute coronary syndrome (ACS) patients at risk for future cardiovascular events. TRANSFORM: Accelerating Lipid Lowering Post ACS (TRANSFORM: ACS) will ensure ACS patients quickly receive cholesterol testing in the hospital and guidelinerecommended therapies to reduce LDL-C in the hospital and upon discharge.

ACC is mission driven to transform cardiovascular care for all patients, and this novel approach should reduce the risk of recurrent major adverse events.

Athena Poppas, MD, FACC

The primary goal of the TRANSFORM: ACS program will be to improve the rate of lipid-panel testing and lipid-lowering treatment intensification in ACS patients within 75 days after hospital discharge. Rapid cholesterol testing after a cardiovascular event within the hospital is hypothesized to drive initiation of lipid-lowering treatment within the first year post ACS, which could increase compliance and help patients avoid events more rapidly than current standard of care.

"Research has noted gaps in optimal care delivery for ACS patients. Our collaborative study will investigate mechanisms for early initiation, and test pilots for close follow-up, of lipid-lowering therapies," says ACC President **Athena Poppas**, **MD**, **FACC**. "ACC is mission driven to transform cardiovascular care for all patients, and this novel approach should reduce the risk of recurrent major adverse events." The project will have two phases. Phase one will focus on supporting in-hospital lipid-lowering treatment of post-ACS patients as recommended, while phase two will evaluate quality improvement by following discharged ACS patients into the outpatient care setting to evaluate trends in treatment and risk prevention for up to a year post-discharge.

TRANSFORM: ACS will leverage the NCDR Cath PCI and Chest Pain – MI hospital registries, along with the Allscripts outpatient EHR and the PINNACLE Registry, operated by Veradigm in association with the ACC, to identify hospitals for intervention as well as affiliated outpatient clinics. Additionally, MedAxiom will develop a protocol with participating hospitals to certify clinician and health system engagement and retainment, ensuring goals of this program are met.

"LDL-C is one of the most important modifiable risk factors in reducing the risk of another cardiovascular event and studies have shown that many people who are at very high-risk, including those with ACS, are not being treated to the ACC/ AHA guidelines and more intensive efforts are needed," says Cesar Cerezo Olmos, MD, PhD, vice president of Global and US Medical for Amgen's General Medicine business unit. "Supporting TRANSFORM: ACS represents our commitment to helping patients with cardiovascular disease improve outcomes, as well as our proactive approach to care designed to predict and help prevent another potentially life-altering CV event from happening."

This initiative is the latest under the TRANSFORM umbrella. TRANSFORM programs leverage clinical registry data, office-based interventions and partnerships to include the pharmaceutical and medical device industry, health plans, employers, clinicians and patients.

Two New Expert Consensus Decision Pathways Address HFrEF, Same-Day Discharge After PCI

he ACC has released two separate Expert Consensus Decision Pathways. The first provides guidance and recommendations on streamlining clinical care to achieve optimal outcomes for patients with heart failure with reduced ejection fraction (HFrEF) and the second addresses same-day discharge after PCI. Both were published in the Journal of the American College of Cardiology.

The HFrEF Pathway aims to address 10 "pivotal" issues that remain unresolved in clinical guidelines. Specifically, the Pathway looks at how to implement guideline-directed medical therapy; how to address specific challenges like referral, care coordination, specific patient cohorts, etc.; and how to manage areas of increasing complexity, comorbidities and palliative care. According to the authors, new therapies for HFrEF have emerged that expand the armamentarium for the treatment of patients with HFrEF since the original Pathway was published in 2017. As a result, the updated Pathway incorporates two new recommendations for patients with HFrEF, including the up-from use of sacubitril/valsartan without an angiotensin-converting

enzyme inhibitor/angiotensin receptor blocker pre-treatment. The second recommendation is for the use of a sodium-glucose cotransporter-2 inhibitor for care of patients with HFrEF, with or without diabetes.

Recent improvements

in safety and efficacy have made it possible for same-day discharge to occur following PCI with select adult patients. The ACC's other new Pathway includes a checklist of clinical, social and facility/systems factors that clinicians can use to help determine whether a patient can be safely considered for same-day discharge. It also highlights the benefits of same-day

discharge after PCI in leading to efficient resource utilization, including increased inpatient bed availability and reduced costs related to supplies and room and board.

Scan the QR code to access the new pathway and checklist.

Scan the

OR code

NCDR: Advancing Patient Care and Outcomes

To improve patient outcomes, we must accurately measure, reliably compare, and constantly improve the quality of care we deliver," write ACC President Athena Poppas, MD, FACC, and NCDR Oversight Committee Chair Frederick A. Masoudi, MD, MSPH, FACC, in a JACC Leadership Page highlighting the ways ACC's NCDR registries are consistently delivering on this aspirational goal.

In addition to helping hospitals, practices and institutions improve the care provided to patients, Masoudi and Poppas underscore the value inherent in registry-derived research, as well as the integration of education and quality improvement activities into the registry experience. They also offer a glimpse at the future of the NCDR, and a focus going forward on four objectives:

- 1. Reducing the burden of data collection while exploring additional sources of data.
- 2. Enhancing NCDR value to stakeholders.
- 3. Promoting local, regional, national and international quality improvement.
- 4. Supporting population health management through advocacy and generalizable information.

Visit CVQuality.ACC.org for more on NCDR, as well as ACC Accreditation Services and Quality Campaigns.

Number Check

DEEP DIVE INTO THE DATA: A CLOSER LOOK AT CVD WORLDWIDE

As we approach American Heart Month, new estimates of the global burden of cardiovascular disease (CVD) increase the urgency of actions to transform cardiovascular practice and improve heart health. Learn more about these numbers from the Global Burden of Diseases, Injuries, and Risk Factors Study 2019 and what they mean for cardiovascular practice in this month's cover story starting on page 20.

30%

The percentage of smokers worldwide from China. Nearly 1/3 of all tobaccoattributable deaths occurred in China.

The number of prevalent cases of total CVD in 2019, nearly double from 271 M in 1990.

8.9 M

30 to 70

Total number of CVD deaths among women in 2019, compared with 9.6 M among men.

The age range with the greatest

number of CVD deaths (6.1 M).

~50%

The proportion of deaths attributed to air pollution that are caused by CVD. Source: Newman JD, Bhatt DL, Rajagopalan S, et al. *J Am Coll Cardiol* 2020;76:2878-94.

6-Fold

The decrease in age standardized mortality rates in Japan in 2019 compared with 1990. France and Peru joined Japan in having the lowest age-standardized mortality rates worldwide.

10

The number of underconsumed food types – fruits, vegetables, legumes, whole grains, nuts/seeds, milk, fiber, calcium, omega-3 fatty acids from seafood and polyunsaturated fats – identified by the paper. Red meat, processed meat, sugar-sweetened beverages, trans-fatty acids and sodium were the five most overconsumed food types.

8

The number of modifiable risk factors identified by the paper, including high systolic blood pressure, dietary risks, high LDL-C, air pollution, high BMI, smoking, high blood sugar and kidney dysfunction.

5

The number of countries identified by the paper with the highest number of CVD deaths (China, India, Russian Federation, U.S. and Indonesia).

Same-Day Discharge After PCI: New Expert Consensus Decision Pathway

new ACC Expert Consensus Decision Pathway aims to address the uncertainty around same-day discharge after PCI and provides a checklist of clinical, social and facility/systems factors that clinicians can use to help determine whether a patient can be safely considered for same-day discharge.

The Pathway, published in the Journal of the American College of Cardiology, provides an overview of the evolution of PCI and resulting improvements in safety and

efficacy that make it possible for same-day discharge to occur with select adult patients without observed increases in other complications, mortality and readmissions. It also highlights the benefits of same-day discharge after PCI in leading to efficient resource utilization, including increased inpatient bed availability and reduced costs related to supplies and room and board.

The Pathway also outlines pre- and post-PCI considerations for successful same-day discharge, as well as pre-discharge processes, including confirmation of the patient's receipt of a P2Y12 inhibitor prescription, instructions on how to monitor the access site, and confirmation that the patient has appropriate outpatient follow-up scheduled.

According to the writing committee led by Chair **Sunil V. Rao, MD, FACC**, and Vice

Chair **Mladen I. Vidovich, MD, FACC**, "the ideal time to begin the checklist is before the procedure, but depending on the workflow and resources of individual institutions, the checklist may also be started and completed after the procedure."

Rao, Vidovich, et al., note that the checklist is developed in a way that it can be adapted to fit the needs and processes of individual institutions.

FIGURE 1. Summary Graphic: Clinical, Patient, and Systems/Staff Factors to Consider Before and After PCI When Deciding on Same-Day Discharge

Graphic depiction showing the factors that affect the decision for same-day discharge for PCL Pre-procedural and post-procedural considerations, including patient social factors, patient clinical factors, staft/system factors, and completion of discharge checklist all influence the decision on SDD,

NSTEMI = non-ST-elevation myocardial infarction; P2Y₁₀ = P2Y₁₀ inhibitors; PCI = percutaneous coronary intervention; SDD = same-day discharge; STEMI = ST-elevation myocardial infarction.

They stress that the instructions should "be adapted to conform with the protocols of individual institutions" and note that success of a same-day discharge program will be dependent on a team approach that involves shared decision-making with the patient.

Rao SV, Vidovich MI, Gilchrist IC, et al. J Am Coll Cardiol 2021; Jan 7: [Epub ahead of print].

Amyloidosis in Hospitalized HF Patients Associated With Worse Outcomes

he presence of cardiac amyloidosis in patients hospitalized with heart failure (HF) may be associated with higher rates of inpatient mortality and 30-day readmissions, according to a study published in *JACC: CardioOncology*.

Sameer Arora, MD, MPH, et al., reviewed 1,593,360 hospitalizations with a primary diagnosis of HF between 2010 and 2015. Of the patients hospitalized for HF, 2,846 (0.18%) had a secondary diagnosis of amyloidosis. These patients were then matched to 8,515 patients hospitalized for HF without amyloidosis. Of the

matched patients, 63% were men and the median age was 75 years. Those with amyloidosis were more likely than those without amyloidosis to have malignancy (20% vs. 4%) and kidney disease (56% vs. 45%). Patients with amyloidosis had lower prevalence of chronic pulmonary disease, diabetes, history of myocardial infarction, peripheral vascular disease, coronary artery disease, hypertension and obesity.

Results showed that the primary outcome of inpatient mortality was 6% in patients with amyloidosis vs. 3% in those without amyloidosis. Among those with amyloidosis, 30-day readmission was 24% vs. 21% in those without. In unadjusted analysis, HF with amyloidosis was associated with higher odds of in-hospital morality (odds ratio [OR], 1.46; 95% confidence interval [CI], 1.17-1.82) and 30-day readmissions (OR, 1.17; 95% CI, 1.05-1.31).

The increased likelihood of readmission in those with amyloidosis was

largely driven by readmission for noncardiovascular reasons. There was no significant between-group difference in cardiovascular-related readmissions. Patients with amyloidosis had a longer length of stay.

"With the advent of new life-prolonging therapies for cardiac amyloidosis, these results emphasize the need to develop more effective screening strategies to facilitate early diagnosis of amyloidosis in HF patients," conclude the study authors.

They study confirms that amyloidosis "is significantly underdiagnosed among patients admitted with decompensated HF," **Karen E. Joynt Maddox, MD, MPH, FACC**, and **Kathleen W. Zhang, MD**, **FACC**, write in an accompanying

editorial comment. They add that "a national effort is needed to better care for these patients, who are at high risk for missed diagnosis and treatment."

Arora S, Patil NS, Strassle PD, et al. JACC CardioOncology 2020;2:710-8.

Call For Papers: Heart Failure and Diabetes

JACC: Heart Failure invites submissions for a focus issue on diabetes and heart failure planned for August of 2021. Submissions are due April 2. Learn more in the new JACC

Journals Author Center at JACC. org/Author-Center or scan the QR code.

How is Cardio-Oncology Advancing in Japan?

ancer and cardiovascular disease are the leading causes of death in Japan, a country with a rapidly increasing elderly population. While Japan has made progress in reducing cancer mortality, there has been an increase in the number of cancer survivors. Consequently, Japan is seeing an increase in cardiovascular events related to cancer treatment. To address the growing field of cardio-oncology in Japan, **Issei Komuro, MD, PhD,** president of the Japanese Onco-Cardiology Society, published two perspectives Dec. 15 in *JACC: CardioOncology*.

In the first paper, Komuro and **Chikashi Ishioka, MD, PhD**, president of the Japanese Society of Medical Oncology, discuss the growing demand for

treatment of cancer patients with cardiovascular comorbidities or complications. They explain that cardiologists need information and knowledge of current cancer therapies; and in turn, oncologists require the same information and knowledge of cardiovascular disease. The Japanese Onco-Cardiology Society was established in 2017 to further strengthen col-

laboration between cardiologists and oncologists to move cardio-oncology forward. The medical societies led by Komuro and Ishioka will continue to work together to create registries and increase an exchange of views between cardiologists and oncologists to design and conduct studies, as well as develop evidence-based guidelines for cardio-oncology. "Our societies will continue efforts to reduce the growing burden of cardiovascular disease and cancer and to make cardio-oncology blossom in Japan," they write.

In the second paper, Komuro, **Toru Oka, MD, PhD,** et al., discuss how Japan has focused on reducing the burden of cancer by creating 402 cancer hospitals since 2007. In 2010, the first "onco-cardiology" unit was launched as part of growing awareness of the cardiovascular impacts on outcomes and quality of life in cancer patients and survivors. Since the inaugural unit, cardiooncology units have become more widespread in Japan. Medical societies within the country are working together to further establish these units to provide high-quality medical care and coordinate medical education, training and research across the globe. According to the authors, "the importance of cardio-oncology will definitely continue to increase more and more in Japan, where an epidemic of cancer and cardiovascular disease is emerging because of the aging of the population."

Komuro I, Ishioka C. *JACC CardioOncology* 2020;2:819-21. Oka T, Akazawa H, Sase K, et al. *JACC CardioOncology* 2020;2:815-8.

Are HF Patients Hospitalized With COVID-19 At Greater Risk of Death?

early one in four patients with heart failure (HF) hospitalized with COVID-19 die during hospitalization, based on findings from a study published in *JACC: Heart Failure*. Study authors note their results highlight the need for "targeted infection control measures and novel care pathways" in this high-risk group.

Ankeet S. Bhatt, MD, MBA, Karola S. Jering, MD, et al., analyzed data from 132,312 patients in the Premier Healthcare Database with at least one hospitalization for HF or two HF-related outpatient visits between Jan. 1, 2019 and March 31, 2020, and who were subsequently hospitalized between April and September 2020. Researchers compared baseline characteristics, health care resource utilization and mortality rates between those patients hospitalized for COVID-19 and patients hospitalized for other causes. Multivariate logistic regression was used to identify predictors of in-hospital mortality.

Results found a total of 23,843 patients (18%) were hospitalized with acute HF, 8,383 patients (6.4%) were hospitalized with COVID-19 and 100,068 patients (75.6%) were hospitalized for other causes between April and September 2020. Of those patients hospitalized with COVID-19, 24.2% died in the hospital vs. 2.6% of those hospitalized with acute HF. According to the authors, advanced age, morbid obesity and diabetes were among the predictors of death in HF failure patients hospitalized with COVID-19.

"Hospitalization with COVID-19 in patients with [HF] is associated with particularly high health care resource utilization and in-hospital mortality," the authors wrote. They stress the importance of "structured data collection to determine COVID-19 prevalence across ongoing and planned randomized clinical trials in [HF]" moving forward and note "the prevalence of COVID-19 in each individual trial may drastically influence interpretation of regulatory trial data."

In a related editorial comment, **Ersilia M. DeFilippis, MD, Mitchell A. Psotka, MD, PHD, FACC**, and **Nasrien E. Ibrahim, MD, FACC**, write that patients with HF in the study who were hospitalized for COVID-19 "were more likely to identify as Black and/or Hispanic, consistent with previous evidence of the disproportionate burden of COVID-19 infection on underrepresented minorities."

Bhatt AS, Jering KS, Vaduganathan M, et al. JACC Heart Fail 2021;9:65-73.

Does Increasing Female, Minority Mentors Increase Success and Diversity in Cardiology?

fforts to increase the number and visibility of female and underrepresented minority cardiology mentors may have the potential to shift the demographics within the field of cardiology and lead to increased diversity and sex balance, according to a paper published in *JACC: Basic to Translational Science*.

Islam Abudayyeh, MD, MPH, FACC, et al., conducted a survey of ACC cardiologists to assess career mentor activity and success, as well as identify the areas of greatest need. The survey was completed by 508 cardiologists. Questions focused on demographics, mentor experience, metrics of success, professional development and job satisfaction.

Results showed that mentees are more satisfied with their mentorship experience when they have had more than three mentors or a mentor from outside of their practice or institution. The authors note that a higher number of mentors may reflect an increased likelihood of finding a "good fit" mentor, and that having a mentor outside of one's institution may reflect increased networking. In addition, the characteristics that mentees desire in a mentor tended to change with time and career stage.

Importantly, survey results also showed that satisfaction with the men-

toring relationship is significantly associated with perceived satisfaction in achieving professional goals.

Furthermore, the authors found that gender and race concordance in mentoring relationships was associated with positive outcomes, as well as an important variable to increase diversity in cardiology.

"Although our findings also support sex and race/

ethnic concordance in mentoring relationships, sample sizes were small for some subgroups," the authors conclude. "Thus, additional research is needed to more thoroughly investigate the effect of sex and race on mentoring, career success, and professional satisfaction."

How Do Health Outcomes of Wealthy White Americans Compare With Average U.S. Citizens and Other Countries?

hile health outcomes of White Americans living in the richest counties are better than those of average U.S. citizens, the outcomes are not consistently better than those of average residents in many other developed countries, according to findings from a comparative effectiveness study published in JAMA Internal Medicine.

"Even if everyone achieved the health outcomes of White US citizens living in the 1% and 5% richest counties, health indicators [in the US] would still lag behind those in many other countries," the study authors write.

The study conducted by **Ezekiel** J. Emanuel, MD, PhD, Emily Gudbranson, BA, et al., analyzed data from White citizens living in the 1% (n=32) and 5% (n=157) highest-income counties in the U.S. between Jan. 1. 2014 and Dec. 31, 2015 and measured health outcomes related to infant and maternal mortality, colon and breast cancer, childhood acute lymphocytic leukemia, and acute myocardial infarction (AMI). These data were then compared with outcomes among average U.S. residents and all residents in 12 other developed countries, including Australia, Austria, Canada, Denmark, Finland, France, Germany, Japan, the Netherlands, Norway, Sweden and Switzerland.

Overall findings showed White U.S. citizens in the 1% and 5% highest-income counties obtained better health outcomes than average U.S. citizens, but had worse outcomes for infant and maternal mortality, colon cancer, childhood acute lymphocytic leukemia and AMI compared with average citizens of other developed countries.

The authors note that the 5-year survival rate for breast cancer among White U.S. women in the highest-income counties was 92.0%, higher than in all 12 comparison countries – likely due to the push for mammogram screenings in the U.S.

According to the authors, their findings underscore that being well off and White in the U.S. are associated with better health outcomes than those experienced by average US citizens, yet at the same time being well off and White does not guarantee the world's best health outcomes.

They also point out that "even if the dramatic and pervasive inequalities in the provision of U.S. health care across race/ethnicity and socioeconomic status were resolved so that every U.S. citizen experienced health outcomes consistent with those of privileged U.S. citizens, the U.S. would still not rank among the best of comparison countries." They write these findings "suggest — but do not prove – that health outcomes depend on the system of care, rather than the performance of individual physicians or hospitals."

JAMA Viewpoint Underscores Disproportionate Number of Black Men and Women in Medicine

The disproportionate effect of the novel coronavirus on African Americans and communities of color has shone a new light on the more than century-old struggle to increase the number of Black physicians in the

U.S.," writes **Valerie Montgomery Rice**, **MD**, in a viewpoint published in *JAMA*. According to Montgomery Rice, president and dean of Morehouse School of Medicine in Atlanta, GA, "the U.S. has failed to adequately increase the number of Black physicians since the turn of the 20th century," with total Black enrollment in U.S. medical schools hovering around 7% since 2013.

Among the barriers to medical school enrollment for underrepresented minorities is the Medical College Admission Test (MCAT). According to Montgomery Rice "the MCAT score has not been shown to significantly predict whether students will successfully progress in their medical education," yet has an adverse influence on Black applicants. She writes: "More medical schools should focus less on their rankings, such as in the US News and World Report, and should more intentionally embrace their stated missions of diversity and inclusion, using MCAT scores as only one determinant in the selection process, and admitting more of these students. This approach could potentially lead to 3,000 more Black physicians either practicing or in the training pipeline in the U.S. today."

In a related editorial, **Clyde W. Yancy, MD, MACC**, and **Howard Bauchner, MD**, call for a bold new model to fully address diversity in medicine that includes establishing a new medical school at a historically Black college and university. "This new medical school concept provides a needed near-term solution that definitely enhances capacity and, when added to the ongoing commitment to increase diversity in existing medical schools, amounts to real change," they write. They note the challenge will be summoning the will to do it, but stress that the current system as configured will continue to fail with a "significant increase in capacity and a bold and different approach."

Montgomery Rice V. JAMA 2021;325:23-4.

Use of MV PCI Increases, But Still Used in Minority of STEMI Patients, NCDR Study Finds

se of multivessel (MV) PCI among STEMI patients increased through early 2018, but was used in a minority of patients and with wide variations across the U.S., according to a study published in JAMA Cardiology. The study is part of ACC's Research to Practice (R2P) initiative, which identifies impactful cardiovascular research and analyzes its implications for contemporary clinical practice using ACC's NCDR clinical registries.

Eric A. Secemsky, MD, FACC, et al., used data from ACC's CathPCI Registry to examine temporal trends and institutional variation in use of MV PCI among patients with STEMI and MV disease. The researchers looked at all admissions between July 2009 and March 2018 in which patients received primary PCI for STEMI within 12 or fewer hours of presentation or PCI within 24 or fewer hours of thrombolysis and also had MV disease.

Among all STEMI admissions, 359,879 (35.2%) were included in the study. Of these, 138,380 (38.5%) received MV PCI within 45 days. Among patients receiving MV PCI, 42,629 (30.8%) were performed during the index procedure, 43,696 (31.6%) during the index hospitalization and 52,055 (37.6%) within 45 days. Complete revascularization was performed in 105,389 (76.2%) of those who underwent MV PCI. Use of MV PCI declined by 10% from the third quarter of 2009, when the rate was 42.7%, to the second quarter of 2013, with the rate was 32.7%, followed by an increase to 44% in the fourth guarter of 2017. The authors found substantial variation in the in MV PCI across institutions, with a median use of 37.9%.

MV PCI use increased during the study period, but was used in a

Visit ACC.org/Latest-in-Cardiology for additional journal coverage, including Journal Scans and Trial Updates, handpicked weekly by the ACC.org Editorial Board led by Kim Eagle, MD, MACC.

minority of patients and with wide variations across institutions, the researchers explain. They conclude that moving forward, "continued adoption of new trial results into guidelines and practice may further promote the growth of MV PCI."

In an accompanying editorial

commentary John A. Bittl, MD,

FACC, notes that the difference of 11 percentage points between the periods with lowest and highest uptake of MV PCI "probably reflects the belief throughout all periods that culpritonly PCI is the default strategy, with preemptive PCI on nonculprit vessels

being reserved for special circumstances." He adds that Secemsky, et al., "should be commended for showing that culprit-only PCI is the preferred approach in practice and routine multivessel PCI is unpropitious."

Secemsky EA, Butala N, Raja A, et al. JAMA Cardiol Nov 4:[Epub ahead of print].

For millions of appropriate patients struggling with lipid management,¹⁻³ you can help **BLAZE A T TO THEIR LDL-C GOAL**

NEXLETOL and NEXLIZET: Oral, once-daily, nonstatin therapies^{2,3}

In clinical trials:

- NEXLETOL delivered an 18% mean reduction in LDL-C (compared to placebo) when added to maximally tolerated statin dose $(P<0.001)^{2*}$
- NEXLIZET delivered a 38% mean reduction in LDL-C (compared to placebo) when added to maximally tolerated statin dose (P<0.001)
- Incidence of most common adverse reactions for both NEXLETOL and NEXLIZET were generally comparable to placebo²
- Bempedoic acid, a component of NEXLETOL and NEXLIZET, showed an incidence of skeletal muscle adverse reactions comparable to placebo

For more information about NEXLETOL and NEXLIZET, visit NEXLETOLHCP.com

INDICATION

NEXLETOL and NEXLIZET are indicated as adjuncts to diet and maximally tolerated statir therapy for the treatment of adults with heterozygous familial hypercholesterolemia or hed atherosclerotic cardiovascular disease who require additional lowering of LDL-C. into a different control can under a different different additional lowering of EDE-cions of Use: The effect of NEXLETOL and NEXLIZET on cardiovascular morbidity and ity has not been determined.

IMPORTANT SAFETY INFORMATION Contraindications: NEXLETOL has no contraindications. NEXLIZET is contraindicated in nts with a known hypersensitivity to ezetimibe tablets. Hypersensitivity reactions ding anaphylaxis, angioedema, rash, and urticaria have been reported with ezetim Warnings and Precautions: Hyperuricemia: Bempedoic acid, a component of NEXLETOL and NEXLIZET, may increase blood uric acid levels. Hyperuricemia may occur early in treatment and persist throughout treatment, and may lead to the development of gout,

especially in patients with a history of gout. *Tendon Rupture*: Bempedoic acid is associated with an increased risk of tendon rupture, most commonly involving the biceps tendon, rotator cuff, or Achilles tendon. Tendon rupture occurred within weeks to months of starting bempedoic acid. Tendon rupture may occur more frequently in patients over 60 years of age, patients taking corticosterc or fluoroquinolone drugs, patients with renal failure and patients with previous tendon

Adverse Events: In NEXLETOL clinical trials, the most commonly reported adverse events were upper respiratory tract infection, muscle spasms, hyperuricemia, back pain, abdominal pain or discomfort, bronchitis, pain in extremity, anemia, and elevated liver enzymes. Events reported less frequently, but still more often than in placebo, included benign prostatic hyperplasia and atrial fibrillation. In the NEXLIZET clinical trial, the most commonly reported adverse events observed with NEXLIZET, but not observed in clinical trials of bempedoic acid or ezetimibe, a component of NEXLIZET.

of NEXLIZET, and occurring more frequently than in placebo, were urinary tract infection, nasopharyngitis, and constipation. Adverse events reported in clinical trials of ezetimibe, and occurring at an incidence

eater than in placebo, included upper respiratory tract infection, diarrhea, arthralgia, nusitis, pain in extremity, fatigue, and influenza. Other adverse events reported in postmarketing use of ezetimibe included hypersensitivity reactions, including anaphylaxis, angioedema, rash, and urticaria; erythema multiforme; myalgia; elevat creatine phosphokinase; myopathy/rhabdomyolysis; elevations in liver transaminas

depression; headache; cholelithiasis; cholecystitis.

poratory Tests: Treatment with bempedoic acid was associated with persistent changes in laboratory tests within the first four weeks of treatment, including increases in the and blood urea nitrogen, decreases in hemoglobin and leukocytes, increases let counts, increases in liver enzymes (AST and/or ALT), and increases in creatine

LDL-C changes from baseline (LS mean) in CLEAR Harmony: NEXLETOL: -17% (n=1,488); placebo: +2% (n=742).

IMPORTANT SAFETY INFORMATION (cont.) Laboratory test values generally returned to baseline following discontinua of treatm

Drug Interactions

ovastatin and Pravastatin: Concomitant use with bempe loic acid results in increased concentrations and increased risk of simvastatin or pravastatin-related myopathy. Use of either NEXLETOL or NEXLIZET with greater than 20 mg of astatin or 40 mg of pravastatin should be avoided

Sinvastation of 40 mg of pravastation should be avoided. *Cyclosporine*: Caution should be exercised when using NEXLIZET and cyclosporine concomitantly due to increased exposure to both ezetimibe and cyclosporine. Monitor cyclosporine concentrations in patients receiving NEXLIZET and cyclosporine. In patient treated with cyclosporine, the potential effects of the increased exposure to ezetimibe from concomitant use should be carefully weighed against the benefits of alterations in lipid levels provided by NEXLIZET.

Fibrates: Coadministration of NEXLIZET with fibrates other than fenofibrate is not recommended. Fenofibrate and ezetimibe may increase cholesterol excretion into the

bile, leading to cholelithiasis. If cholelithiasis is suspected in a patient receiving NEXLIZET and fenofibrate, gallbladder studies are indicated and alternative lipid-lowering therapy should be considered.

Cholestyramine: Concomitant use of NEXLIZET and cholestyramine decreases ezetimibe concentration. This may result in a reduction of efficacy. Administer NEXLIZET either at least 2 hours before, or at least 4 hours after, bile acid sequestrants.

Special Populations: It is not recommended that NEXLETOL or NEXLIZET be taken during breastfeeding. A pregnant patient should consult with their healthcare provided about whether to continue treatment during the pregnancy. The safety and efficacy of NEXLETOL and NEXLIZET have not been established in patients under the age of 18. Patients over 65 accounted for nearly 60% of patients in NEXLETOL clinical trials and

50% of patients in the NEXLIZET clinical trial. No adjustments in dosing are required for age, or for patients with mild or moderate renal impairment or mild hepatic impairment for NEXLETOL or NEXLIZET. No adjustments in dosing are required for patients with moderate hepatic impairment for NEXLETOL. NEXLIZET is not recomm with moderate or severe hepatic impairment. ended for patients

NEXLETOL and NEXLIZET are available only by prescription. To report SUSPECTED ADVERSE REACTIONS, contact FDA at 1-800-FDA-1088 or

www.fda.gov/medwatch or ESPERION at 833-377-7633 (833 ESPRMED) kinase. Laboratory abnormalities generally did not require medical intervention. Please see adjacent Brief Summary.

LDL-C changes from baseline (LS mean) in 053 Trial: NEXLIZET: -36% (n=86); placebox +2% (n=41). LDL-C changes from baseline (LS mean) for other drugs in the trial: NEXLETOL: -17% (n=88); ezetimibe: -23% (n=86).

LLEAR Harmony (Study 1) was a 52-week, randomized, double-blind, Phase 3 trail in 2,230 patients randomized 21 to receive NEXLETO (n=1.488) or placebo (n=7.42). (LEAR Harmony included patients aged 218 years with fasting LDL-C #70 mg/dL, and high-risk patients with ASCVD and/or HeFH. NEXLETOL was added to whatever patient's maximally tolerated statin dose was, either alone or with other lipid-lowering therapies. Primary endpoint was general safety, which included adverse reactions, clinical safety laboratories, physical examinations, vital signs, and electrocardiogram. Second

was 12-week, not more a more of the set of t References: 1. Wong ND, Young D, Zhao Y, et al. Vaping Plus Smoking as Harmful as Smoking Alone

moking traditional cigarettes in addition to using e-cigarettes results in harmful health effects similar with smoking cigarettes exclusively, according to a study published in Circulation.

In a data analysis of more than 7,100 U.S. adults ages 18 and older, researchers studied the association

of cigarette smoking and e-cigarette use with biomarkers of inflammation and oxidative stress, key contributors to smoking-induced cardiovascular disease.

Of the study participants, 58.6% did not use cigarettes or e-cigarettes; nearly 2% vaped exclusively; about 30% smoked cigarettes exclusively;

and about 10% used e-cigarettes and traditional cigarettes.

The results found a similar inflammatory and oxidative stress profile in participants who vaped exclusively and those who did not smoke cigarettes or use e-cigarettes. Higher levels across all biomarkers were seen in participants who smoked exclusively and those who used cigarettes plus e-cigarettes vs. those

who never used either.

"I believe [this study] has an important message for individuals who may believe using e-cigarettes while continuing to smoke some combustible cigarettes reduces their risk," says study co-author Rose Marie Robertson, MD, FACC.

Xi W, Wilson A, Yang H, et al. Circulation 2020;2020;Jan 4[Epub ahead of print].

NEXLETOL[®] (bempedoic acid) tablets and NEXLIZET[™] (bempedoic acid and ezetimibe) tablets Professional Brief Summary. Please consult package inserts for full Prescribing Information. INDICATIONS AND USAGE

INDICATIONS AND USAGE NEXLETOL and NEXLIZET are indicated as adjuncts to diet and maximally tolerated statin therapy for the treatment of adults with heterozygous familial hypercholesterolemia or established atherosclerotic cardiovascular disease who require additional lowering of LDL-C. Limitations.of Use: The effect of NEXLETOL and NEXLIZET on cardiovascular morbidity and mortality has not been determined. CONTRAINDICATIONS

NEXLETOL: None. NEXLIZET: NEXLIZET is contraindicated in patients with a known hypersensitivity to ezetimibe tablets *fsee Adverse Reactions*]. Hypersensitivity reactions including anaphylaxis, angioedema, rash and urticaria have been reported with ezetimibe. **WARNINGS AND PRECAUTIONS**

rash and urticaria have been reported with ezetimibe. WARNINGS AND PRECAUTIONS Hyperuricemia Bempedoic acid, a component of NEXLETOL and NEXLIZET, inhibits renal tubular OAT2 and may increase blood uric acid levels. In clinical trials, 26% of bempedoic acid-treated patients with normal baseline uric acid values (versus 95% placebo) experienced hyperuricemia one or more times, and 3.5% of patients experienced clinically significant hyperuricemia reported as an adverse reaction (versus 11% placebo). Increases in uric acid levels usually occurred within the first 4 weeks of treatment initiation and persisted throughout treatment. After 12 weeks of treatment, the mean placebo-adjusted increase in uric acid compared to baseline was 0.8 mg/dL for patients treated with bempedoic acid. Elevated blood uric acid may lead to the development of gout. In clinical trials, gout was reported in 1.5% of patients treated with bempedoic acid rest for gout events was higher in patients with a prior history of gout (11.2% bempedoic acid versus 1.7% placebo), although gout also occurred more frequently than placebo in patients treated with bempedoic acid who had no prior gout history (1.0% bempedoic acid versus 0.3% placebo). Advise patients to contact their healthcare provider if symptoms of hyperuricemia occur. Assess serum uric acid whon clinically indicated. Monitor patients for signs and symptoms of hyperuricemia, and initiate treatment with urate-lowering drugs as appropriate. **Tendon Rupture** Bempedoic acid, a component of NEXLETOL and NEXLIZET, is associated with an increased risk of tendon rupture or injury. In clinical trials tendon rupture occurred in 0.5% of patients treated with bempedoic acid. Tendon rupture our crured within weeks to months of starting bempedoic acid. Tendon or upture occurred within weeks to months of starting bempedoic acid. Tendon or upture may occur more frequently in patients with renal failure, and in patients with previous tendon disorders. Discontinue NEXLETOL on NEX

age, in those taking controsterold or involopting or using a set of the set o

AVERSE REAL HONS The following clinically significant adverse reactions are described elsewhere in the labeling: Hyperuricemia [see Warnings and Precautions] Tendon Rupture [see Warnings and Precautions]

Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials other drug and may not reflect the rates observed in clinical practice

NEXLETCL: The data described below reflect exposure to NEXLETCL in two placebo-controlled trials that included 2009 patients treated with NEXLETCL for 52 weeks (median treatment duration of 52 weeks). The mean age for NEXLETCL treated patients was 65.4 years, 29% were women, 3% were Hispanic, 95% White, 3% Black, 1% Asian, and 1% other races. All patients received NEXLETOL 180 mg orally once daily plus maximally tolerated statin therapy alone or in combination with other lipid-lowering therapies. At baseline, 97% of patients had clinical atherosclerotic cardiovascular disease (ASCVD) and about 4% had a diagnosis of heterozygous familial hypercholesterolemia (HeFH). Patients on simvastatin 40 mg/day or higher were excluded from the trials.

Adverse reactions led to discontinuation of treatment in 11% of NEXLETOL-treated patients and 8% of placebo-treated patients. The most common reasons for NEXLETOL treatment discontinuation were muscle spasms (0.5% versus 0.3% placebo), diarrhea (0.4% versus 0.1% placebo), and pain in extremity (0.3% versus 0.0% placebo). Adverse reactions reported in at least 2% of NEXLETOL-treated patients and more frequently than in placebo-treated patients are shown in Table 1

Table 1. Adverse Reactions (≥ 2% and Greater than Placebo) in NEXLETOL-Treated Patients with ASCVD and HeFH (Studies 1 and 2)

Adverse Reaction	NEXLETOL + Statin and ± Other Lipid Lowering Therapies (N = 2009) %	Placebo (N = 999) %
Upper respiratory tract infection	4.5	4.0
Muscle spasms	3.6	2.3
Hyperuricemiaª	3.5	1.1
Back pain	3.3	2.2
Abdominal pain or discomfort ^b	3.1	2.2
Bronchitis	3.0	2.5
Pain in extremity	3.0	1.7
Anemia	2.8	1.9
Elevated liver enzymes ^c	2.1	0.8

a. Hyperuricemia includes hyperuricemia and blood uric acid increased.
 b. Abdominal pain or discomfort includes abdominal pain, abdominal pain upper, abdominal pain lower, and abdominal discomfort.
 c. Elevated liver enzymes includes AST increased, ALT increased, hepatic enzyme increased, and liver function test increased

liver function test increased

Tendon Rupture Jenom Rupture Bempedoic acid was associated with an increased risk of tendon rupture, occurring in 0.5% of bempedoic acid-treated patients versus 0% of placebo-treated patients.

Gouit Bempedoic acid was associated with an increased risk of gout, occurring in 1.5% of bempedoic acid-treated patients versus 0.4% of placebo-treated patients. Benign Prostatic Hyperplasia Bempedoic acid was associated with an increased risk of benign prostatic hyperplasia (BPH) or prostatomegaly in men with no reported history of BPH, occurring in 1.3% of bempedoic acid-treated patients versus 0.1% of placebo-treated patients. The clinical significance is unknown. <u>Atrial Eibrillation</u> Bempedoic acid-treated patients versus 1.1% of placebo-treated patients. Laboratory Tests Bempedoic acid-treated patients versus 1.1% of placebo-treated patients. Laboratory Tests

of treatment. Increase in Creatinine and Blood Urea Nitrogen: Overall, there was a mean increase in serum creatinine of 0.05 mg/dL compared to baseline with bempedoic acid at Week 12. Approximately 3.8% of patients treated with bempedoic acid had blood urea nitrogen values that doubled (versus 1.5% placebo), and about 2.2% of patients had creatinine values that doubled (versus 1.5% placebo), and about 2.2% of patients had creatinine values that increased by 0.5 mg/dL (versus 1.1% placebo). Decrease in Hemoglobin and Leukocytes: Approximately 5.1% of patients treated with bempedoic acid (versus 2.3% placebo) had decreases in hemoglobin levels of 2 or more g/dL and below the lower limit of normal on one or more occasion. Anemia was reported in 2.8% of patients treated with bempedoic acid and 1.9% of patients treated with placebo. Hemoglobin decrease was generally asymptomatic and did not require medical intervention. Decreased leukocyte count was also observed.

was also observed. Approximately 9.0% of bempedoic acid-treated patients with normal baseline leukocyte count had a decrease to less than the lower limit of normal on one or more occasion (versus 6.7% placebo).

Count had a decrease to less than the lower limit of normal on one of more occasion (Versus 6.7% placebo). Leukocyte decrease was generally asymptomatic and did not require medical intervention. In clinical trials, there was a small imbalance in skin or soft tissue infections, including cellulitis (0.8% versus 0.4%), but there was no imbalance in other infections. Increase in Platelet Count: Approximately 10.1% of patients treated with bempedoic acid (versus 4.7% placebo) had increases in platelet counts of 100×10⁹/L or more on one or more occasion. Platelet count increase was asymptomatic, did not result in increased risk for thromboembolic events, and did not require medical intervention. Increase in Liver Enzymes: Increases in hepatic transaminases (AST and/or ALT) were observed with bempedoic acid. In most cases, the elevations were transient and resolved or improved with continued therapy or after discontinuation of therapy. Increases to more than 3× the upper limit of placebo patients, and increases to more than 5× ULN occurred in 0.4% of bempedoic acid-treated versus 0.2% of placebo-treated patients. Increases in ALT occurred with similar increases to acid-treated patients. Increases in ALT occurred with similar increases to acid-treated patients. Increases in ALT occurred with similar increases to acid-treated patients. Elevations in transaminases were generally asymptomatic and not associated with levations ≥ 2× ULN in bilirubin or with cholestasis. with cholestasis.

with cholestasis. Increase in Creatine Kinase: Approximately 1.0% of patients (versus 0.6% placebo) had elevations of CK levels of 5 or more times the normal value on one or more occasions, and 0.4% of patients (versus 0.2% placebo) had elevations of CK levels of 10 or more times. Ezetimiba: In 10 double-blind, placebo-controlled clinical trials, 2396 patients with primary hyperlipidemia (age range 9-86 years, 50% women, 90% Caucasians, 5% Blacks, 3% Hispanics, 2% Asians) and elevated LDL-C were treated with ezetimibe 10 mg/day for a median treatment duration of 12 weeks (range 0 to 39 weeks). Adverse reactions led to discontinuation of treatment in 3.3% of ezetimibe-treated patients. The most common reasons for ezetimibe treatment

and 2.9% of placebo-treated patients. The most common reasons for ezetimibe treatment discontinuation were arthralgia (0.3%), dizziness (0.2%), and gamma-glutamyltransferase increased (0.2%). Adverse reactions reported in \geq 2% of patients treated with ezetimibe and at an incidence greater than placebo in placebo-controlled studies of ezetimibe, regardless of causality assessment, are shown in Table 2

Table 2. Clinical Adverse Reactions Occurring in ≥ 2% of Patients Treated with Ezetimibe and at an Incidence Greater than Placebo, Regardless of Causality

Adverse Reaction	Ezetimibe 10 mg (%) N = 2369	Placebo (%) N = 1159
Upper respiratory tract infection	4.3	2.5
Diarrhea	4.1	3.7
Arthralgia	3.0	2.2
Sinusitis	2.8	2.2
Pain in extremity	2.7	2.5
Fatigue	2.4	1.5
Influenza	2.0	1.5

The frequency of less common adverse reactions was comparable between ezetimibe

NEXLIZET: In a 4-arm, 12-week, randomized, double-blind, placebo-controlled, parallel group factorial trial, 85 patients received NEXLIZET (180 mg of benedic and 10 mg of ezetimibe) once daily. The mean age for NEXLIZET-treated patients was 62 years, 51% were women, 12% Hispanic, 78% White, 19% Black, and 2% Asian. At baseline, 61% of patients had clinical atherosciencia cardiovascular disease (ASCVD) and/or a diagnosis of heterozygous familial hypercholesterolemia. All patients received NEXLIZET plus maximally tolerated statin therapy. Patients taking simvastatin 40 mg/day or higher and patients taking non-statin lipid-lowering therapy (including fibrates, niacin, bile acid sequestrants, ezetimibe, and PCSK9 inhibitors) were avoluded from the train. excluded from the trial

Adverse reactions led to discontinuation of treatment in 8% of patients on NEXLIZET. 5% of patients on placebo, 10% of patients on bempedoic acid, and 12% of patients on reactimibe. The most common reason for NEXLIZET treatment discontinuation was oral discomfort (2% NEXLIZET versus 0% placebo). The most commonly reported adverse reactions (incidence (∠/0 NEALIZE I VERSUS U% placebo). The most commonly reported adverse reactions (incidence ≥ 3% and greater than placebo) observed with NEXLIZET, but not observed in clinical trials of bempedoic acid or ezetimibe, were urinary tract infection (5.9% NEXLIZET versus 2.4% placebo), nasopharyngitis (4.7% NEXLIZET versus 0% placebo), and constipation (4.7% NEXLIZET versus 0% placebo).

Subcutaneous ICDs Increasing in Dialysis Patients With Low Complication Rates, NCDR Study Shows

se of subcutaneous ICDs in dialysis patients has been steadily increasing, with overall low complication rates compared with transvenous ICDs, according to a study published in the Clinical Journal of the American Society of Nephrology.

Patrick H. Pun, MD, et al., used data from ACC's ICD Registry to examine overall trends in subcutaneous ICD adoption among eligible dialysis patients between September 2012 when subcutaneous ICDs first

Postmarketing Experience With Ezetimibe Because these reactions are reported voluntarily from a population of uncertain size, it is generally not possible to reliably estimate their frequency or establish a causal relationship to drug exposure The following additional adverse reactions have been reported in postmarketing experience for ezetimibe: Hypersensitivity reactions, including anaphylaxis, angioedema, rash, and urticaria; erythema multiforme; myalgia; elevated creatine phosphokinase; myopathy/rhabdomyolysis; elevations in liver transaminases; hepatitis; abdominal pain; thrombocytopenia; pancreatitis; nausea; dizzines; paresthesia; depression; headache; cholelithiasis; cholecystitis. DRUG INTERACTIONS DRUG INTERACTIONS

DRUG INTERACTIONS No specific pharmacokinetic drug interaction studies with NEXLIZET have been conducted. Drug interactions that have been identified in studies with bempedoic acid or ezetimibe determine the interactions that may occur with NEXLIZET. Simvastatin: <u>Clinical Impact</u>: Concomitant use of NEXLETOL or NEXLIZET with simvastatin causes an increase in simvastatin concentration and may increase the risk of simvastatin-related myopathy. <u>Intervention</u>: Avoid concomitant use of NEXLETOL or NEXLIZET with simvastatin greater than 20 mg.

myopathy. Intervention: Avoid concomitant use of NEXLÉTOL or NEXLIZET with simvastatin greater than 20 mg. Pravastatin: Clinical Impact: Concomitant use of NEXLETOL or NEXLIZET with pravastatin causes an increase in pravastatin concentration and may increase the risk of pravastatin-related myopathy. Intervention: Avoid concomitant use of NEXLETOL or NEXLIZET with pravastatin greater than 40 mg. Cyclosporine: Clinical Impact: Concomitant use of NEXLIZET and cyclosporine increases ezetimibe and cyclosporine concentrations. Intervention: Monitor cyclosporine increases ezetimibe and cyclosporine concentrations. Intervention: Monitor cyclosporine concentrations in patients receiving NEXLIZET and cyclosporine. In patients treated with cyclosporine, the potential effects of the increased exposure to ezetimibe from concomitant use should be carefully weighed against the benefits of alterations in lipid levels provided by NEXLIZET. Fibrates: Clinical Impact: Both fenofibrate and ezetimibe may increase cholesterol excretion into the bile, leading to cholelithiasis. Coadministration of NEXLIZET with fibrates other than fenofibrate is not recommended. Intervention: If cholelithiasis is suspected in a patient receiving NEXLIZET and fenofibrate, galibladder studies are indicated and alternative lipid-lowering therapy should be considered. Cholestyramine: Clinical Impact: Concomitant use of NEXLIZET and cholestyramine decreases ezetimibe concentration. This may result in a reduction of efficacy. Intervention: Administer NEXLIZET either at least 2 hours before or at least 4 hours after bile acid sequestrants. USE IN SPECIFIC POPULATIONS Pregnancy

USE IN SPECIFIC POPULATIONS Pregnancy Discontinue NEXLETOL or NEXLIZET when pregnancy is recognized unless the benefits of therapy outweigh the potential risks to the fetus. There are no available data on bempedoic acid use in pregnant women to evaluate for a drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes. There are no available data on bempedoic acid use in pregnant women to evaluate for a drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes. There are insufficient data on ezetimibe use in pregnant women to evaluate for a drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes. In animal reproduction studies, bempedoic acid was not teratogenic in rats and rabbits when administered at doses resulting in exposures up to 11 and 12 times, respectively, the human exposures at the maximum clinical dose, based on AUC. In oral (gavage) embryo-fetal development studies of ezetimibe conducted in rats and rabbits during organogenesis, there was no evidence of maternal toxicity or embryo-fetal teratogenic or toxicologic effects at exposures up to 10 and 150 times the human exposure, respectively, based on AUC (see *Data*). NEXLETOL and NEXLIZET decrease cholesterol synthesis and possibly the synthesis of other biologically active substances derived from cholesterol; therefore, NEXLETOL and NEXLIZET may cause fetal harm when administered to pregnant women based on the mechanism of action. In addition, treatment of hyperlipidemia is not generally necessary during pregnancy. Atherosclerosis is a chronic process and the diverse transmission of action in the organ during pregnancy active base interimet on so at the site or topical to base in the mechanism of action. Automitistered to pregnant women based on the mechanism of action. In addition, treatment of hyperlipidemia is not generally necessary during pregnancy. Atherosclerosis is a chronic process and the discontinuation of lipid-lowering drugs during pregnancy should have little impact on the outcome of long-term therapy of primary hyperlipidemia for most patients. The estimated background risk of major birth defects and miscarriage for the indicated population is unknown. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2-4% and 15-20%, respectively. Data Data

<u>Animal Data</u> Bempedoic acid

Bempedoic acid was not teratogenic when given orally at doses of 60 and 80 mg/kg/day, resulting in 11 and 12 times the systemic exposure in humans at the maximum recommended human dose (MRHD) of 180 mg to pregnant rats and rabbits, respectively. In an embryofetal development study in rats, bempedoic acid was given orally to pregnant rats at 10, 30, and 60 mg/kg/day during the period of organogenesis from gestation day 6 to 17. There were increases in the incidence of non-adverse fetal skeletal variations (bent long bones and bent manual to the period of organogenesis from gestation to the division of the state of the second state of the second terms of the second second second second second terms of the second second second second terms of the second second second terms of the second second second terms of the second terms of terms of terms of terms of terms of the second terms of scapula and incomplete ossification) at doses ≥ 10 mg/kg/day (less than the clinical exposure) in the absence of maternal toxicity. At maternally toxic doses, bempedoic acid caused decreases In the numbers of viable fetuses, increases in post-implantation loss, and increased total resortions at 60 mg/kg/day (11 times MRHD) and reduced fetal body weight at \geq 30 mg/kg/day (4 times the MRHD). No adverse development effects were observed when bempedoic acid was given to pregnant rabbits during the period of organogenesis (gestation day 6 to 18) at doses up to 80 mg/kg/day (12 times MRHD).

to so mg/kg/day (12 times inkHD). In a pre- and post-natal development study in pregnant rats given oral doses of bempedoic acid at 5, 10, 20, 30 and 60 mg/kg/day throughout pregnancy and lactation (gestation day 6 to lactation day 20), there were adverse effects on delivery in the presence of maternal toxicity, including: increases in stillborn pups, reductions in numbers of live pups, pup survival, pup growth and slight delays in learning and memory at \geq 10 mg/kg/day (at exposures equivalent to the mg/kg/day (at exposures equivalent to the MRHD) Ezetimibe

In oral (gavage) embryo-fetal development studies of ezetimibe conducted in rats (gestation days 6-15) and rabbits (gestation days 7-19) during organogenesis, there was no evidence of maternal toxicity or embryolethality at any of the doses tested (250, 500, 1000 mg/kg/day) at exposures equivalent to 10 to 150 times the MRHD, based on AUC, in rats and rabbits. In rats, International to the polerating at any of the bosis tested (250, 500, 100, 100 mg/kg/day) at exposures equivalent to yoternating at any of the bosis tested (250, 500, 100 mg/kg/day) at increased incidences of common fetal skeletal findings (extra pair of thoracic ribs, unossified cervical vertebral centra, shortened ribs) were observed at 1000 mg/kg/day (approximately 10 times the human exposure at 10 mg daily based on AUC, _{0.200}, for total ezetimibe). In rabits treated with ezetimibe, an increased incidence of extra thoracic ribs was observed at 1000 mg/kg/day (150 times the human exposure at 10 mg daily based on AUC, _{0.200}. For total ezetimibe). In rabits treated with ezetimibe, an increased incidence of extra thoracic ribs was observed at 1000 mg/kg/day (150 times the human exposure at 10 mg daily based on AUC, _{0.200}. For total ezetimibe). The animal-to-human exposure an till mg daily based on AUC, _{0.200} for total ezetimibe). The animal-to-human exposure at 01 mg daily based on AUC, _{0.200}. For total exetimibe, bit and the statis conducted using a maternal dose of 1000 mg/kg/day. The fetal maternal plasma exposure ratio (total ezetimibe) was 1.5 for rats on gestation day 20 and 0.03 for rabbits on gestation day 22. The effect of ezetimibe on prenatal and postnatal development and maternal function was evaluated in pregnant rats at doses of 100, 300 or 1000 mg/kg/day (gestation day 6 through lactation day 21). No maternal toxicity or adverse development al outcomes were observed up to and including the highest dose tested (17 times the human exposure at 10 mg daily based on AUC, _{0.200} for total ezetimibe).

Multiple-dose studies of ezetimibe coadministered with statins in rats and rabbits during organogenesis result in higher ezetimibe and statin exposures. Reproductive findings occur at lower doses in combination therapy compared to monotherapy. Bempedoic acid/ezetimibe fixed combination drug product (FCDP) In a combination embryofetal development study in rats, bempedoic acid and ezetimibe were given orally at 4 and 112-times MRHD (based on AUC) during the period of organogenesis (gestation day 6 to 17) in pregnant rats. Bempedoic acid in combination with ezetimibe did not alter the effects on embryo-fetal development profile of bempedoic acid or ezetimibe. **Lactation** Risk Summary There is no information regarding the presence of bempedoic acid in human or animal milk, the effects of the drug on the breastfed infant, or the effects of the drug on milk production. There is no information about the presence of ezetimibe in human milk. Ezetimibe is present in rat milk (see Data). When a drug is present in animal milk, it is likely that the drug will be present in rat milk. There is no information about the effects of ezetimibe on the breastfed infant or the effects on milk production. NEXLETOL and NEXLIZET decrease cholesterol synthesis and possibly the synthesis of other biologically active substances derived from cholesterol and may cause harm to the breastfed infant. Because of the potential for serious adverse reactions in a breastfed infant, based on the mechanism of action, advise patients that breastfeding is not recommended during treatment with NEXLIZETOL or NEXLIZET. Data Animal Data Zama Animal Data Cause have a spresent in the milk of lactating rats. The pup to maternal plasma ratio for total

Lata <u>Animal Data</u> Ezetimibe was present in the milk of lactating rats. The pup to maternal plasma ratio for total ezetimibe was 0.5 on lactation day 12. **Pediatric Use** The safety and effectiveness of NEXLETOL and NEXLIZET have not been established in pediatric notiontr.

pediatric patients. Geriatric Use 0f the 3009 patients in clinical trials of NEXLETOL, 1753 (58%) were 65 years and older, while 478 (16%) were 75 years and older. Of the 301 patients in the clinical trial of NEXLIZET, 149 (50%) were 65 and over, while 49 (16%) were 75 and over. No overall differences in safety or effectiveness were observed between these patients and younger patients, and other reported clinical experience has not identified differences in responses between the elderly and younger patients. However, greater sensitivity of some older individuals cannot be ruled out.

Renal Impairment No dosage adjustment is necessary for either NEXLETOL or NEXLIZET in patients with mild or moderate renal impairment. There is limited experience with bempedoic acid in patients with severe renal impairment (eGFR < 30 mL/min/1.73 m²), and it has not been studied in patients with end-stage renal disease (ESRD) receiving dialysis.

With end-stage renal disease (cand) receiving data set. **Hepatic Impairment** No dosage adjustment is necessary for NEXLETOL in patients with mild or moderate hepatic impairment (Child-Pugh A or B), or for NEXLIZET in patients with mild hepatic impairment (Child-Pugh A). NEXLIZET is not recommended in patients with moderate or severe hepatic impairment (Child-Pugh B or C) due to the unknown effects of the increased exposure to ezetimible. NEXLETOL has not been studied in patients with severe hepatic impairment ("bild Pugh C) (Child-Pugh C).

There is no clinical experience with NEXLETOL or NEXLIZET overdosage. In the event of overdose, contact Poison Control (1-800-222-1222) for latest recommendations.

became available - and March 2018, and compare in-hospital outcomes among dialysis patients receiving subcutaneous ICDs vs. transvenous ICDs. For the comparative analysis, the researchers limited the cohort to only dialysis patients who met criteria for a subcutaneous ICD and were hospitalized for an elective first-time ICD implantation. The primary outcome was the composite of any

in-hospital adverse events.

During the study period, there were 23,135 ICD implantations among dialysis patients. Of these patients, 3,195 (14%) received subcutaneous devices. Subcutaneous devices accounted for about 5% of all ICD implantations at the beginning of the study, compared with 20% of all ICD implantation procedures in 2018.

For the comparative analysis, there were 1,539 patients who received subcutaneous ICDs and 1,788 who received transvenous ICDs. Among these patients, use of subcutaneous devices increased from 10% of all implants in 2012 to 69% of all implants in 2018. Before propensity scoring, subcutaneous ICD recipients were younger, more likely to be Black, and less likely to be from southern states. The composite of any in-hospital adverse event was not statistically different between those receiving subcutaneous ICDs (2.39 events per 100 implantations) vs. transvenous ICDs (1.48 events per 100 implantations). However, patients receiving subcutaneous devices were more likely to experience in-hospital cardiac arrest vs. those receiving transvenous ICDs.

According to the researchers, the study shows an overall low complication rate in dialysis patients who receive subcutaneous ICDs. While the low complication rate supports use of subcutaneous devices in eligible dialysis patients, they note that "potential benefits of lower long-term infection risk and reduction in central venous stenosis, compared with transvenous ICD, have not been proven." Moving forward, longer-term studies are needed to determine the risk-benefit and cost-effectiveness of subcutaneous ICDs in this population, they conclude.

Feature

TAVR and SAVR: Different Strategies For Different Folks?

Transcatheter aortic valve replacement (TAVR) for high-risk, older patients with severe aortic stenosis is now standard therapy. Its expanded use in other patient populations – including younger patients with lower risk – has been tested in several randomized trials. Many now think that TAVR should be a universal therapeutic first choice – but do the data really support this stance? This month *Cardiology* takes a look at the evidence for determining which patients are best suited for TAVR, based on what the data show, and which patients are perhaps still better served by surgical aortic valve replacement (SAVR).

TAVR: From Then Until Now

n a little less than a decade, we have experienced a major paradigm shift in the management of patients with severe, symptomatic aortic stenosis (AS). Starting in 2011, with the first commercial approval of TAVR by the U.S. Food and Drug Administration (FDA), more than 300,000 patients have been treated in the U.S.

Although it currently seems as if a tsunami is occurring, actually it has been a 31-year journey since the initial idea was conceived by **Henning Andersen, MD, PhD,** a cardiologist in Aarhus, Denmark. Milestones along this journey include the first series of animal implantations that were presented as a poster at the European Society of Cardiology Congress in 1992, the first human TAVR implantation by **G. Alain Cribier, MD,** in Rouen, France, in 2002 and the first U.S. experience in 2004.

The Evidence

In the U.S., two series of investigational device exemption (IDE) randomized trials leading to FDA approval started in 2007. These regulatory approval trials, the PARTNER trials of the balloon-expandable Sapien Valve (Edwards Lifesciences, Irvine, CA) and the CoreValve/Evolut Trials (Medtronic, Inc., Minneapolis, MN) of a self-expanding valve led to the initial FDA approval of TAVR in 2011 and reimbursement coverage by the Centers for Medicare and Medicaid Services (CMS) in 2012.

These series of trials have enrolled a total of 9,682 patients, of which 8,098 have been randomized to TAVR with a control of either medical therapy or SAVR. This has resulted in a robust evidence base that led to hundreds of peer reviewed publications, including 10 articles in the New England Journal of Medicine and two in The Lancet.

The two series of trials started in inoperable patients, finding that TAVR was superior to medical therapy. The subsequent trials in high risk and intermediate surgical risk patients all found that TAVR was noninferior to SAVR. The latest of the trials in patients with low surgical risk presented and published in 2019, found that TAVR was either superior to or noninferior to SAVR at one and two years.^{1,2} Ten year follow-up is planned for both trials.

The Now

All commercially implanted TAVR devices in the U.S., with the exception of government hospitals, are entered into the STS/ACC TVT Registry, a condition of reimbursement by a National Coverage Determination (NCD) issued by CMS.

According to registry data, there are currently 716 centers in the U.S. performing TAVR, and in 2019 there were approximately 75,000 patients treated.³ The demographics and outcomes of patients treated in the real-world setting largely mirrors those patients treated in the pivotal trials (**Figure 1**). It was estimated that there would be a 20-25% further increase in TAVR implantations in 2020 resulting in a total of 90,000 to 100,000 patients undergoing the procedure. However, the impact of the COVID-19 pandemic has attenuated that continued procedural growth by an estimated 20%.

The Candidates

Based on trial evidence, the decision regarding appropriate candidates for TAVR should no longer be based on the patient's risk for a surgical procedure. Rather, the patient's age should be the basis for the initial decision (**Figure 2**).

In a possible decision pathway, the first decision is to determine whether the patient is better suited for a tissue valve or a mechanical valve. Current guidelines recommend a mechanical valve for patients <55 years and a tissue valve for patients >65 years with shared decision-making based on patient's preference being the determining factor in patients between 55 and 65 years.⁴

If a patient is deemed to be best suited for a tissue valve, the next decision is determining whether the patient is best treated by TAVR or SAVR. There were very few patients younger than 65 years (<10%) enrolled into any of the low risk TAVR trials, so we lack a robust body of evidence in younger patients. Currently most patients >80 years are best treated with TAVR and those 65

Figure 1	Low-Risk	Patients F	Receiving	TAVR in the	"Real-World vs	. Pivotal Trials

	TVT Registry	Low Risk Trial #1	Low Risk Trial #2
Number of Patients Receiving TAVR	8,385 in 2019 (7,101 in 2nd half of 2019)	496 (as treated cohort)	725 (as treated cohort)
Age of Patients	Median 75 years (IQR 70,81)	Mean 73 years	Mean 74 years
Sex	65% Male	67.5% Male	66% Male
Race	93% White	NA	92% White
STS PROM Score	Median 2.3% (IQR 1.6, 3.45)	Mean 1.9%	Mean 1.9%
Baseline NYHA Class 3 and 4	48.9%	31.2%	25.1%
Femoral Access	97.8%	100%	100%
Length of Hospital Stay	Median 1 (IQR 1,2)	Mean 3 days	NA
In-Hospital Mortality	0.5%	0.4%	NA

years or younger by SAVR, with individual patient preferences and patient comorbidities and valve path-anatomic factors informing the decision in for patients between 65 and 80 years.

The path-anatomic factors for consideration in patients 65 and 80 years include trial exclusions such as patients with bicuspid aortic valves, extensive left ventricular outflow tract calcium, asymptomatic patients and those with complex concomitant coronary artery disease. Therefore, SAVR should be the preferred approach in these patients who have a reasonable surgical risk. In addition, other patients who are at high risk for TAVR include those with low-lying coronary artery orifices or requiring an alternative access approach and there should be strong consideration for SAVR.

The Unanswered Questions

Other evidence gaps regarding TAVR to be addressed include the greater need for a new permanent pacemaker, which becomes more important in younger patients, and a higher incidence of new left bundle branch block which has been determined to be a risk factor for long-term mortality.

The issue of valve thrombosis and need for anticoagulation is another unanswered guestion. In a recent FDA-mandated CT substudy of the low-risk trials, there was imaging evidence of valve thrombus in 20-28% of patients undergoing both TAVR and SAVR by one year.⁵ Most of these were not associated with a clinical event and the need for anticoagulation remains unclear. A recent trial of rivaroxaban in TAVR was stopped early due to safety issues, yet a 4D CT substudy of this trial showed there was a lower incidence of valve thrombosis in the treatment arm.^{6,7}

Durability is yet another unanswered concern. Currently, there is no significant signal of structural valve deterioration up to five years. However, very few patients are alive after five years, although some patients in the NOTION trial have been followed to eight years. In the patients in the low-risk TAVR trials, we only have two-year follow-up data. But all these patients will be followed annually for 10 years to help answer the question of the durability of tissue valves in both TAVR and SAVR.

The use of TAVR in bicuspid aortic valves, especially in younger patients, remains an evidence gap. And it remains to be determined what evidence will be generated to indicate which patients with bicuspid aortic valves can be treated safely with TAVR and which patients should be preferentially treated with SAVR.

The Role of SAVR

Despite the widespread adoption of TAVR, SAVR will continue be a necessary and important part of the treatment of patients with aortic stenosis (Figure 3). It is estimated that in the near future, one of three or four patients undergoing aortic valve replacement will still be best treated with SAVR. This includes patients with extensive coronary artery disease, other valvular disease,

dilation of the ascending aorta, young patients with bicuspid aortic valves and, of course, endocarditis.

The next few years will also see an increasing number of patients presenting for a surgical procedure after a previous TAVR. Early experience with surgery in these patients indicates that the complexity of the surgical procedure will be greater when explantation of a TAVR device is necessarv.

Summary

In a little less than a decade, we have seen a major paradigm shift in the management of aortic stenosis. It has been truly remarkable to see the rapid adoption of a procedure that is widely applicable to a large number of patients who are able to be treated in a safe and effective manner by a broad cadre of practitioners.

Structural Heart Disease Intervention: Quo Vadis?

nterventional therapies for cardiac pathology have advanced at a rapid and accelerating rate during the last decade and are now legion. During the latter half of the last century there was a rapid expansion of surgical solutions which more recently have been standardized, promoting reliable and durable results. This is now the era of safe and reproducible surgery. and deterioration, the incidence of significant para-prosthetic leaks and patient-prosthesis mismatch. Current mortality should be very low with rates of less than 1% mortality and six days or less length of hospital postoperative stay being almost the rule in good centers, and excellent and durable quality of life is now the norm. However, all is not perfect. Remember, the elephant in the room

The advent of minimal access and percutaneous procedures have altered the landscape irreversibly, often, but not always for the good. The trend towards the apparent universal dissemination of coronary angioplasty and stenting applied in a staged approach has been replaced by the demonstration of the superiority of surgery in certain defined groups; this, plus the advent of the "heart team" operating within the confines of a good evidence base has resulted in a balanced approach with a more appropriate use of surgery and catheter-based procedures to the betterment of patient outcomes.

A new revolution is happening now in the management of heart valve disease. Effective therapies for the mitral and aortic valves are evolving quickly and whilst short-term outcome data are being generated and published, some in the form of randomized-controlled trials, meaningful mid- to long-term data (five to 15 years) is absent. Conversely, while the vast surgical experience is short on controlled prospective data, it is replete with long-term of the performance of most important extant valve types.

Data at 15 and 20+ years are available for valve replacement and valve reconstruction. A great deal is known about prosthetic valve function is there is no such thing as "surgery," there are only "surgeons" and their results are variable. Hence the need for specialist centers.

Variable results between surgeons and centers continue and poor surgery results in the complications raised above. A recent paper reported a mortality of 3.6% for SAVR in a study which contrasted this with the results for TAVR, portraying SAVR in a poor light.¹ However, the quoted incidence of mortality is at a level that would cause horror in quality institutions. (Current mortality for all-comers for AVR in our hospital runs at 0.8% and we believe this can be improved upon). Hospital length of stay is an average of five days and para-prosthetic leaks and early valve failure are rare. Contrast this with TAVR where mortality is also low, but para-prosthetic leaks and pacemaker use are high and mid- to long-term failure rate remains largely unknown.

In the mitral arena, reconstructive surgery of the "degenerative" valve is now the norm in most expert centers where expertise is focused in fewer, expert hands. Repair rates exceeding 90% are expected with a mortality of less than 1%.¹ Mitral valve replacement with complete subvalve preservation is similarly an excellent procedure with well-defined and excellent long-term outcomes.

Into this arena steps percutaneous interventions that are as yet not well tested outside a few specialist centers. The Mitraclip, where the opposing leaflets are fixed together producing a double-orifice valve, has now secured approval in some countries and institutions. Its initial use has been in patients otherwise deemed too high risk for surgery and patients with functional mitral regurgitation resulting in satisfactory initial results in controlling and/or reducing the amount of mitral regurgitation. However, several learning points from the surgical groups are being ignored. One is that ischemic mitral regurgitation is a ventricular disease which will progress as ventricular degeneration continues causing a return of mitral regurgitation. With a surgical approach, multiple procedures exist to mitigate against this including annuloplasty, papillary muscle approximation and ventricular wall plication. Indeed, the most recent studies have shown superiority of mitral valve replacement with subvalvular preservation in the worst cases.

Its move into degenerative cases is being enhanced by poorly controlled mitral valve surgery in some centers where repair in even infirm elderly patients can be achieved with excellent permanent results in the correct surgical hands. It can be argued that all of this reveals a focus on the careers of some professionals rather than what is best for patients. One has to ask how much professional empowerment and perhaps arrogance plays over the Hippocratic stance of first do no harm on both sides of this particular fence.

Thus, what should be the way ahead? First, the use of such devices is discussed by a well-informed heart team. Second, ready access to the evidence base. Third, the prospective collection of all data. With this in place, the best plan for each patient can be formed. Finally, it is vital that the patient is given a full review of the discussion surrounding their case, not "edited highlights" to enable them to make the best decision for themselves.

And, cardiologists, do not forget that the more routine surgery keeps surgeons in practice for the more difficult problems whence many patients will still need their skills.

Editor's Note: Turn to page 2 for an editorial on patient selection for TAVR and pages 34-35 for recommendations for TAVR and more from the newly released ACC/AHA Guideline on Valvular Heart Disease.

GLOBAL TRENDS IN CVD BURDEN Understanding the Scope

to Devise Solutions

he number of people dying from cardiovascular disease (CVD) is steadily rising, encompassing one-third of all deaths globally in 2019, according to a landmark paper published last month in the Journal of the American College of Cardiology (JACC).

The paper, which uses data from The Global Burden of Diseases, Injuries, and Risk Factors Study 2019 (GBD 2019), reviews the total magnitude of CVD burden and trends over 30 years around the world and highlights 13 underlying causes of cardiovascular death and nine related risk factors. It also underscores the urgent need for countries to establish cost-effective public health programs aimed at reducing cardiovascular risk through modifiable behaviors.

This issue of Cardiology offers a closer look at the key findings from the paper and the opportunities for cardiovascular professionals around the world to use the data and knowledge to optimize patient care and outcomes and truly transform global health. Don't miss Number Check on page 6 for more insights from the GBD 2019.

Table Cardiovascular Disease Insights From the GBD 2019 Study

Implication Observation The burden of CVD, measured in Population growth and population number of DALYs, continues to aging will require countries and increase globally. health systems to prioritize the prevention and care of CVD. A rise in the age-standardized rates Subpopulations within countries of CVD DALYs over the past 5 yrs is are experiencing adverse trends in cardiovascular health, suggesting a concerning trend seen in several subnational locations, including a need to support the delivery of parts of the United States, Mexico, interventions in high-risk locations. and the United Kingdom. Globally in 2019, CVD was the underlying cause of >6 million deaths occurring between the ages of 30 and 70 yrs.

CVD is a common cause of premature death among young and middle-aged adults, with 1.2 million CVD deaths in 2019 occurring in those younger than the age of 50

The majority of global CVD burden is attributable to modifiable risk factors.

yrs Inadequate risk factor control is an enormous global problem that demands innovative public health solutions

Global CVD Health and COVID-19

Amid the current COVID-19 pandemic, there exists high rates of excess mortality. According to the paper in *JACC*, much of this additional disease burden may be related to CVD, because of the effects of both viral infection and changes in the delivery of health care and health-seeking behaviors due to pandemic mitigation efforts.

In an Executive Summary accompanying the landmark paper, Gregory A. Roth, MD, MPH, FACC; George A. Mensah, MD, FACC; and Valentin Fuster, MD, PhD, MACC, note that the COVID-19 pandemic and related "large economic setbacks will require renewed commitments to meet Sustainable Development Goal 3, which seeks a 30% reduction in premature mortality due to noncommunicable disease by 2030." They note that "early studies suggest that direct and indirect excess cardiovascular mortality due to the coronavirus disease 2019 pandemic may be large, further stretching already limited investments in global cardiovascular health" and stress the importance of additional research, as well as continued global action.

"In the face of a global viral pandemic, we still must emphasize global commitments to reduce the suffering and premature death caused by CVD, which limits healthy and sustainable development for every country in the world," said Fuster.

In the face of a global viral pandemic, we still must emphasize global commitments to reduce the suffering and premature death caused by CVD, which limits healthy and sustainable development for every country in the world.

– Valentin Fuster, MD, PhD, MACC

Get out your earbuds and listen to JACC Editor-In-Chief Valentin Fuster, MD, PhD, MACC, discuss highlights from the paper in a special podcast.

Cover Story

Global Health: What to Watch

n addition to highlighting global trends in CVD, the Global Burden of Disease paper offers insights into potential actions as well as opportunities going forward to turn the tide on CVD mortality. On the watch list:

• Population growth and aging are likely to increase the total prevalent cases of CVD worldwide, according to the study. In particular, countries in Northern Africa, Latin America and all of Asia are expected to be hardest hit. "Effective and affordable clinical strategies remain overlooked by health systems as targets for investments, including methods for noninvasive screening, use of combination pharmacotherapy medications to lower blood pressure and unhealthy cholesterol levels, investment

There is often a gap between the identification of a problem, the location of a solution and the translation of that solution to an entire population.

- Gregory A. Roth, MD, MPH, FACC; George A. Mensah, MD, FACC; Valentin Fuster, MD, PhD, MACC, et al.

in ambulance services and emergency care including for cardiac arrest, interventional structural and cardiac surgical services including for congenital and rheumatic heart disease, and wider access to rehabilitation services," the authors write.

• **Polypills** continue to be viewed as a possible solution to help control elevated blood pressure and related conditions, particularly in lower-income countries. Most recently, findings from the TIPS-3 study presented at AHA 2020 found the polypill reduced CVD by approximately 20% compared with placebo in people considered at intermediate risk for heart disease. Patients taking both a polypill

plus aspirin saw even greater reductions. According to **Salim Yusuf, MD, BS, DPhil, FACC**, one of the authors of the TIPS-3 study, use of a polypill plus aspirin could prevent 3-5 million cardiovascular deaths globally and "future polypills, with newer statins, may reduce LDL cholesterol and blood pressure to a greater extent and could reduce cardiovascular disease risk greater than 50%." Scan the QR code to read more on the study.

 The prevalence of Rheumatic Heart Disease has been steadily increasing over the last 30 years, reaching 40.5 million in 2019, according to the paper. The authors note that an effective group A streptococcal vaccine could greatly decrease the burden of this disease, especially in low- to middle-income countries. In the meantime, the new ACC/AHA Guideline for Valvular Heart Disease includes recommendations for treating patients with rheumatic fever or evidence of rheumatic heart disease. Scan the QR code to read more about the recommendations.

• Peripheral artery disease (PAD) remains highly prevalent, increasing two-fold between 1990 and 2019. The paper notes that "the burden of PAD is increasing not only in developed [high-income countries] HICs but also in [low- and middle-income countries] LMICs, where concomitant risk factors such as diabetes and obesity are increasing." The authors call for greater regulation and further studies to help prevent and treat this disease.

About the Global Burden of Diseases, Injuries, and Risk Factors Study

A multinational collaborative research effort, the Global Burden of Diseases, Injuries, and Risk Factors Study estimates the burden of disease for every country worldwide. Updated annually, the study provides for consistent comparisons from 1990 to 2019, by age and sex and across locations. New diseases, new data sources and updated methods are included in the annual updates.

Standard epidemiological measures, such as incidence, prevalence and death rates, along with summary measures of health, such as disability-adjusted life-years (DALYs), are provided by the study. DALYs, the years of life lost prematurely and years lived with disability, are estimated using life tables, estimates of prevalence and disability weights.

Air Pollution:

A Modifiable Risk Factor Data from the GBD 2019 reinforce the impact of air pollution on health outcomes, including CVD. Learn more

TOP 10 TAKEAWAYS ON CVD AND RISK FACTORS FROM GBD 2019

By Ragavendra R. Baliga, MBBS, FACC

CVD AND DISABILITY Prevalent cases of total CVD nearly doubled from 271 million in 1990 to 523 million in 2019. The number of CVD deaths steadily increased from 12.1 million in 1990, reaching 18.6 million in 2019. The global trends for disability-adjusted life-years (DALYs) and years of life lost (YLLs) also increased significantly, and years lived with disability (YLDs) doubled from 17.7 million to 34.4 million over that period.

ISCHEMIC HEART DISEASE (IHD) The total number of DALYs due to IHD has risen steadily since 1990, reaching 182 million DALYs and 9.14 million deaths in the year 2019. This new report estimated 197 million prevalent cases of IHD in 2019.

RHEUMATIC HEART DISEASE Rheumatic heart disease burden is highest among the world's disadvantaged populations. Its prevalence has been rising steadily since 1990, reaching 40.5 million currently affected in 2019. Deaths decreased until 2012 and then stabilized but have started increasing since 2017 (306,000 in 2019).

CARDIOMYOPATHY AND MYOCARDITIS The

prevalence and related mortality of cardiomyopathy and myocarditis increase throughout adulthood in both sexes with a larger proportion of cases in men than in women. The increased prevalence associated with aging is more pronounced in cardiomyopathies than in myocarditis. DALYs due to cardiomyopathy and myocarditis have increased from 7.06 million to 9.14 million over the past 30 years, a pattern that is also seen in the rise of deaths from 238,000 to 340,000.

STROKES The total number of prevalent strokes, deaths and DALYs due to stroke increased steadily from 1990, reaching 101 million prevalent stroke survivors (85.3% increase); 6.55 million deaths from stroke (43.3% increase); and 143 million DALYs due to stroke (32.4% increase) in 2019, with the bulk of the burden outside of the high-income world. Of 12.2 million incident stroke cases, 7.63 million (62.4%) were ischemic stroke, 3.41 (27.9%) were intracerebral hemorrhages, and 1.18 million (9.7%) were subarachnoid hemorrhages.

ALCOHOLIC CARDIOMYOPATHY Women are generally considered more susceptible to alcohol-induced damage than men, which may reflect sex-specific differences in alcohol consumption, type, blood level, distribution or metabolism. However, the higher level of alcohol consumption and the higher frequency of alcohol problems among men could justify the observed higher rate of DALYs. The global prevalence of alcoholic cardiomyopathy estimated by the 2019 report was 708,000 cases, approximately 9.1 cases per 100,000. Globally, alcoholic cardiomyopathy was responsible for 71,700 deaths, 2.38 million YLLs, and 60,100 YLDs.

Hypertensive Heart Disease The global prevalence of hypertensive heart disease has risen steadily over the last three decades, as have the total number of deaths, DALYs, YLLs and YLDs due to this disease. In 2019, hypertensive heart disease was the main cause of 1.16 million deaths and 21.5 million DALYs annually, with a global prevalence of 18.6 million cases.

ATRIAL FIBRILLATION AND ATRIAL FLUTTER

(AFIB/AFL) The total number of DALYs due to AFib/ AFL increased progressively from 3.79 million in 1990 to 8.39 million) in 2019. This new report estimated 59.7 million prevalent cases of AFib/AFL in 2019, about a doubling compared to the prevalent cases in 1990. Health systems and countries will need to focus their efforts to reverse these trends by aggressive attention to the reduction of risk factors such as hypertension, diabetes, and obesity; better treatment of individuals with IHD and heart failure; and improved access to medications for thromboembolism prophylaxis.

CONGENITAL HEART DISEASE A total of 3.12 million babies were born with congenital heart anomalies in 2019 representing 2,305.2 per 100,000 live births. A total of 13.3 million people were living with congenital heart anomalies, and this was the underlying cause of 217,000 deaths, of which 150,000 deaths were in infants younger than 1 year.

AORTIC ANEURYSM The total number of YLLs due to aortic aneurysm, including both thoracic and abdominal types, has increased steadily since 1990, reaching 3.32 million YLLs and 172,000 deaths in 2019.

Feature

Where Are They Now: Conversations With the 2020 ACC/Merck Fellowship Awardees

or the last four decades, the ACC and Merck have partnered together to provide research fellowships to nearly 200 cardiovascular clinicians in the early stages of their careers. These fellowships have stimulated and encouraged young scientists to pursue careers in research – many of whom have gone on to play leading roles in both their institutions and the ACC.

Cardiology recently caught up with the 2020 ACC/Merck awardees – **Darae Ko, MD, MSc**, and **Priya M. Freaney, MD** – to talk about their research, highlights to date, next steps and advice to other Fellows in Training and Early Career clinicians. Read their interviews below and see the sidebar for more information on the 2021 Merck Fellowships (the application deadline is Jan. 29) and save the date for ACC.21 in May where the newest awardees will be celebrated as part of Convocation.

Darae Ko, MD, MSc

Assistant Professor in Medicine Boston University

Research and Highlights to Date:

My research project has focused on risk-guided atrial fibrillation (AFib) surveillance in ischemic stroke with the goal of establishing current national practice patterns in the use of an implantable loop recorder (ILR) after ischemic stroke for AFib surveillance.

I hypothesize that the practice patterns are highly variable, and this variability is mostly driven by patients' insurance status, physician subspecialty, and hospital characteristics rather than patient comorbidities. The findings from the project will benchmark post-stroke ILR use and estimate the magnitude of the potential opportunity to optimize ILR use for post stroke AFib detection.

Since the start of the ACC/Merck fellowship in July 2020, I published a paper as a second co-author in the journal *Stroke* investigating the feasibility of using data from electronic health records to phenotype cardioembolic stroke. Perhaps the most exciting news is that I found out recently my NHLBI K23 application received a fundable score.

Key Takeaways From the

ACC/Merck Fellowship Experience The biggest challenge for me during the fellowship was learning how to transition from fellow to faculty. There was a lot of grant writing to secure a faculty position with protected research time. The most important takeaway from this arduous experience is that as an early-career investigator, I could not have done my research without my mentors who believed in me and who wanted to help me. **Emelia J. Benjamin, MD, ScM, FACC**, (cardiology, Boston University), **Allan Walkey, MD, MSc**, (pulmonary and critical care, Boston University), and **Steven Lubitz**, **MD, MPH**, (cardiology, Harvard Medical School) are my closest mentors who consider it their mission to support the next generation of scientists.

Next Steps and Advice For the Future

I will transition to my K23 award after the ACC/ Merck Fellowship ends. The K23 award will allow me to further develop research expertise in AFib and anticoagulation and become an independent researcher. My ultimate goal is to become an R01-funded investigator with a focus on identifying opportunities to improve health care delivery for AFib detection and treatment and developing effective strategies to prevent AFib-related complications.

I cannot emphasize enough the importance having a team of mentors. Mentors can make (or break) the careers of early-stage researchers. If you surround yourself with people who believe in you and want to support you, and you work hard, you will maximize your chance of successfully transitioning to the next stage of your career.

WILL YOU BE NEXT?

The ACC is excited to celebrate the 40th Anniversary of its partnership with Merck. In recognition of this milestone anniversary, ACC and Merck are offering three one-year fellowships totaling \$100,000 each. One of the fellowships will be awarded by the Association of Black Cardiologists (ABC) to a current ABC member pursuing research focusing on disparities of care. Preference for all three awards will be given to individuals who have had no more than two

years of prior full-time experience either in clinical or basic research. Recipients will be expected to pursue a full-time project in clinical research during their year of supported training, beginning July 1, 2021 and ending June 30, 2022. Awardees will be recognized during Convocation at ACC.21 in May.

All applications must be complete and submitted by Jan. 29. Scan the QR code for more information on eligibility, selection criteria and the submission process.

NEW DATES!

ACC.21

Priya M. Freaney, MD

Cardiology Fellow Northwestern University Research and Highlights to Date

The overarching goal of my research is to better understand the role of adverse pregnancy outcomes in the future development of cardiovascular disease (CVD). Adverse pregnancy outcomes include hypertensive disorders of pregnancy, low birthweight of babies, and preterm delivery. Specifically, we aim to understand the association between adverse pregnancy outcomes and subclinical CVD to be able to implement strategies to prevent overt CVD.

In addition to presenting our work demonstrating the association of pregnancies complicated by low birthweight deliveries with adverse maternal heart health (cardiac mechanics) at ACC.20/WCC, I also presented our work on trends and disparities in adverse pregnancy outcomes at the Northwestern Cardiology Young Investigator Forum national conference and received the 3rd place clinical fellow award. I have also co-authored several manuscripts in JAMA, *Circulation: Heart Failure, American Journal of Medicine*, and *Current Atherosclerosis Reports* in the past year.

Key Takeaways From the ACC/Merck Fellowship Experience

The COVID-19 pandemic has certainly introduced challenges during my ACC/Merck fellowship year. As with many other researchers around the world, in-person participant recruitment, data collection and networking opportunities are currently compromised. Luckily, remote research and virtual connections have helped to fill this gap, though we eagerly await the safe return to in-person collaborations in the near future.

In all, however, the ACC/Merck fellowship has been a phenomenal opportunity. It has been incredibly valuable to have a full year of protected research time during my cardiology fellowship to dedicate to advancing my clinical research career. One simple but important message is that high-quality research takes time. I am so grateful to have the opportunity to receive dedicated training at Northwestern University Feinberg School of Medicine in the Department of Preventive Medicine to develop a strong foundation for a future career as a clinician scientist with the support of the ACC/ Merck fellowship.

Next Steps and Advice For the Future

Following my ACC/Merck fellowship year, I plan to continue my research in women's cardiovascular disease prevention, obtain additional training in cardiovascular imaging, and ultimately aim to join or start a Women's Heart Health Center. My goal is to have both clinical and research programs that identify barriers to transitions of care from peripartum obstetric care to postpartum cardiovascular care, screening pathways for premature CVD, and related mechanisms for novel therapeutic targets to improve cardiovascular outcomes in women who have experienced adverse pregnancy outcomes.

I strongly advise any cardiology fellow who is pursuing a career in clinical investigation to apply for the ACC/Merck fellowship. The process of putting together the application alone serves as an opportunity to articulate your vision for a research proposal, and the prestigious fellowship can then launch your career as an early investigator and serve as a bridge to independent funding.

CONVERSATION WITH THE EXPERT

The COVID-19 Pandemic Has Changed Cardiac Telemedicine and Patient Monitoring, But What Will Happen Post-Pandemic?

OVID-19 has greatly impacted the health system since early 2020. In March, many states enacted stay-at-home orders. Many hospitals and health systems temporarily halted elective medical procedures in an effort to mitigate the risk of COVID-19 transmission; preserve personal protective equipment, hospital bed capacity, and equipment; and allow shifts in healthcare staffing patterns.¹

During this time, the use of telemedicine vastly increased. During the first quarter of 2020, the number of telemedicine visits increased by 50% compared to the same period in 2019, with a 154% increase in visits observed in the last week of March 2020 compared to the same period in 2019.² As a result, the Centers for Medicare & Medicaid Services enacted emergency policies related to telemedicine that, among other changes, allowed virtual visits to be conducted from patients' homes rather than in a healthcare setting.^{2,3}

Patients with cardiac conditions are at an increased risk for COVID-19-related morbidity and mortality. Emergency department admissions for heart failure and heart attacks have notably decreased, which may be due to patient reluctance to visit healthcare facilities during the pandemic.⁴

Remote patient monitoring cardiac devices offer a safe solution to telemedicine during the pandemic.⁴ The Zio XT monitor is a prescription-only, single-patient-use, continuously

Clinical discussion with:

Andre Gauri, MD, FHRS Cardiologist and Electrophysiologist Spectrum Health

recording electrocardiogram monitor that can be worn up to 14 days. It is indicated for use on patients who may be asymptomatic or may suffer from transient symptoms such as palpitations, shortness of breath, dizziness, lightheadedness, presyncope, syncope, fatigue, or anxiety.⁵

In response to the pandemic, iRhythm expanded its home enrollment for its Zio single-use cardiac monitors, shipping the devices directly to patients' homes for application and use.⁶ This home enrollment option reduces potential patient and staff COVID-19 exposure by eliminating office visits, removes the need for cleaning or reusing returned monitors that may have been exposed to the virus, and ensures patients continue to receive access to cardiac care during the pandemic.⁷

Clinical Insights

Andre Gauri, MD, FHRS, a cardiologist and electrophysiologist at Spectrum Health in Michigan, discussed how COVID-19 has impacted cardiac care, the role of home monitoring and telemedicine, and the healthcare changes that are still ahead.

How have the surges in COVID-19 infections affected your patients, patient volume, and practice?

When COVID-19 hit the United States, we at Spectrum Health went into partial shutdown mode and limited care to only emergent cases.

We saw what was happening in New York and Detroit where the healthcare system was extremely overwhelmed. Although we had many COVID-19 patients in the spring, we never really overwhelmed our system. Patients were scared to come to the hospital, so many people were deferring care. We quickly realized, in a matter of a few weeks, that we could and needed to safely take care of patients who were not dealing with COVID-19. We had the bandwidth to open our doors again to do more elective and semi-elective procedures. Although we observed a major dip in elective care initially, by mid-May 2020 we were able to successfully ramp up to normal volumes.

When COVID-19 surges occurred again in the fall of 2020, the system was much more prepared given the experiences and lesson learned from earlier in the year. On the cardiac side, very few cases were postponed even though we had almost three to four times as many COVID-19 patients in the hospital compared to the spring. The fact that much of the cardiac care was same-day discharge and not requiring a hospital bed allowed us to care for patients despite a high hospital census.

Can you discuss your process for implementing telemedicine? Were there any challenges?

When the pandemic first hit and most medical groups went into a shutdown, we were only seeing emergent patients in person. Almost everyone was at home seeing patients virtually. On my team of eight electrophysiologists, we had one person assigned to the hospital, one to the office, and the rest were seeing patients virtually.

There's a famous saying, "Don't let a tragedy go to waste," and the pandemic really made providers quickly focus on developing alternatives to care for our patients. We went from seeing a very limited number of patients through telemedicine—approximately 5% of patients mainly in rural areas—to seeing 80% of our patients via telemedicine in a matter of days to weeks. *[Learn more by watching Dr. Gauri share how he and his team maintained continuity of care amid the COVID-19 pandemic at irhythmtech.com/acc.]*

Our existing telemedicine platform wasn't built for that volume, and technical issues surfaced at first. Patients didn't have the right software, didn't have good Wi-Fi, and had difficulties connecting. In talking to colleagues across the country, many people struggled with this as well.

Cardiac electrocardiogram monitoring technologies like Zio by iRhythm also allowed us to mitigate patient concerns about coming to the hospital. Because Zio allows for home enrollment of monitors and sends a comprehensive report at the end of the 14-day patient wear period, we were able to eliminate the need for patients to travel. Zio was instrumental in helping Spectrum make the transition to remote care and telehealth easier. I was really proud of our leadership team coming together, stepping up, and allowing the changes in telehealth to take place that provided continued patient care.

How have you or your team thought through the different monitoring modalities available as you think about adapting to COVID-19?

As an electrophysiologist heart rhythm specialist, many of our patients require monitoring. When COVID-19 started, only urgent patients were coming in the clinic. As we moved to telemedicine, we questioned how we were going to care for patients remotely if we saw they were having symptoms that warranted a cardiac monitor. The Zio monitor really helped us continue to care for and monitor our patients without them ever leaving their homes. That was a tremendous benefit to the arrhythmia patients, driving 98% patient compliance, which in turn provided us with more accurate data.⁸

Another advantage of using these single-use Zio patches is that concerns of transmissible diseases were essentially eliminated. Reuseable Holter monitors require additional cleaning and sterilization due to COVID-19 concerns and possible risk of transmission to both staff and patients.

With COVID-19, have you seen any new patient types?

Researchers are seeing more patients with cardiovascular symptoms stemming from COVID-19, ranging from chest pain to palpitations to presyncope or syncope as well as myocarditis. These are just some of the symptoms that COVID-19 "long-haulers" experience. We anticipate a whole new heart patient population from this group in the future.

Are you seeing a decline in cardiac health in patients delaying care?

Absolutely. In the electrophysiology space, patients who develop atrial fibrillation that is poorly controlled can develop a weakened heart muscle that is related to their atrial fibrillation, known as a tachycardia-induced cardiomyopathy. Patients were having symptoms and not seeking medical attention in the appropriate time frame, coming in with later rather than early presentations of cardiac diseases. When they finally came in due to significant difficulty breathing or walking, they had already developed congestive heart failure.

Delayed presentations also occurred with heart attacks and strokes. A complication from a late presentation of myocardial infarction could be a ruptured papillary muscle, or ventriculoseptal defect, but we rarely see those because most people who have a heart attack present early and get revascularized immediately. We were seeing a tremendous increase in these rare cases because patients weren't coming in for medical attention and not getting revascularized.

These patients are the secondary COVID-19 casualties: They didn't have a problem directly related to COVID-19, but they did develop significant morbidity as a result of not seeking medical attention during the pandemic. Because Zio can be applied at home by the patients themselves, cardiac monitoring does not have to be deferred. Patients will have clinically better outcomes with earlier treatment.

In recent clinical studies, Zio was able to detect atrial fibrillation in moderate-risk patients earlier, supporting the prevention of serious cardiac events after diagnosis. Active monitoring with Zio also led to fewer hospitalizations for bleeding and fewer total hospitalizations.⁹

Active, early monitoring with Zio can help patients stay home and out of the hospital.

What are patients' sentiment now in resuming care?

Fortunately, patients are feeling more comfortable as we learn more about the virus—knowing that if you're safe, wear a mask, and wash your hands, you can still leave your house. We did a lot of public service messaging around continuing to see your doctor if you're having problems. We tried to educate patients that if they're having acute medical issues, they should not delay care. I think that was very helpful in making patients feel more comfortable seeking medical attention.

Still, as we return to in-person care, there are a number of cases that are better suited for remote monitoring; not all cases involve acute medical issues. Our augmentation of telemedicine has freed the in-person resources for the most critical cases. Where do you foresee the role of cardiac monitoring going in 2021? What patient behavior changes do you anticipate post-COVID-19? Cardiac monitoring with iRhythm's home enrollment has been very helpful. If I'm seeing a patient who lives many miles from our office, I'm now seeing that patient via tele-

health. Instead of having to come to get a monitor placed in person, we can do home delivery and home enrollment with Zio. We have developed a system where we can more broadly expand telehealth solutions to patients long-term, not just during the pandemic. There's clear benefit to both the patient and the system here.

Will telehealth increase in popularity or revert to pre-COVID-19 levels?

At our peak, we were seeing probably 70% to 80% of our patients via telehealth. We've learned that many patients would rather see a provider in person if given the choice. The doctor-patient relationship is extremely important yet somewhat diminished via telehealth. Obviously, not being seen at all is worse than being seen over a computer, but I definitely think there's a fine balance.

At the end of the day, there are many people who just want to leave the house and see their doctor in person. I think we will find a balance where maybe 20% to 25% of patients will be seen via telehealth, and the rest would still be seen in person—time will ultimately tell.

For 2021, the American Medical Association released new Current Procedural Terminology (CPT) codes that address longer-term cardiac monitoring. Will this change the way you care for patients?

We have been long-term users and early adopters of long-term cardiac monitoring with iRhythm's Zio monitor. For the first several years, this was a real struggle mainly because of insurers not covering the test because it didn't have a CPT code. Often, patients would get stuck with bills or have to do a lot of backend work to settle their bill in an agreeable fashion. This really is amazing technology that we've been using for almost 10 years now, and I'm so grateful that this payment barrier is finally gone.

I have used many devices over the years, including other mobile cardiac outpatient telemetry systems and patch-type extended Holters. In terms of insurance coverage, it's the type of device that poses potential coverage concerns not the specific device brand. The biggest advantage of the iRhythm products is the format of their device reports. They are structured in an intuitive and concise fashion with clinically relevant information readily available. This significantly reduces the time it takes [me] to interpret a report and make necessary clinical patient care decisions.

Every single atrial fibrillation patient I treat usually has several monitors over the course of their care—pre-ablation, post-ablation, and follow-up. I'm not necessarily going to order more monitors now, but I think it's going to be a lot easier for patients since they are not going to face insurance payment barriers.

What long-term changes do you see taking effect? How do you see the pandemic shaping cardiac care?

From a regulatory and technology standpoint, I see change occurring at a much faster pace. Some of the regulatory restrictions on telemedicine hopefully will no longer exist. There has been a huge boon for third parties developing telehealth technologies that are more patient- and healthcare system-friendly. Many of our patients are elderly and are not very technologically savvy, so you have to make it very easy for them to use. These technologies will allow more real-time health data to be shared with providers and hopefully allow for earlier detection of disease and better management of chronic illnesses such as heart failure and diabetes.

Dr. Gauri is a board-certified cardiologist and electrophysioloaist and is a Fellow of the Heart Rhythm Society. He is the chief of cardiac electrophysiology and medical director of the Atrial Fibrillation Program at Spectrum Health in Grand Rapids, Michigan. He is a clinical assistant professor of medicine at Michigan State University, College of Human Medicine. Dr. Gauri earned his medical degree from Stritch School of Medicine, Loyola University in Maywood, Illinois, and completed his internal medicine residency at Stanford University School of Medicine in Stanford, California. He completed his cardiology fellowship at University of Chicago and completed his electrophysiology cardiology fellowship at Loyola University Medical Center in Maywood, Illinois. Dr. Gauri's clinical interests include catheter ablation of atrial fibrillation and other complex arrhythmias and implantation of pacemakers, cardiac defibrillators, and resynchronization devices.

Dr. Gauri received compensation for his contribution to this initiative.

Making News in 2020

W ithout a doubt, the top news of 2020 was the COVID-19 pandemic. From the beginning, ACC was at the forefront of generating clinical guidance, providing expert commentary and facilitating the sharing of new research and front-line perspectives.

Top articles in 2020 include *Cardiology* magazine features on the risk of infectious agents and an exclusive interview with **Anthony S. Fauci, MD;** ACC's guide to safely resuming cardiovascular procedures, diagnostics and tests; insights from clinicians on the front lines of treating patients in China; and more. ACC's COVID-19 Hub includes links to these articles and much more.

Scan the QR code for the complete list and read the top 10 articles from 2020. Important cardiovascular research didn't stop with the pandemic. Hot clinical trials like VOYAGER-PAD, RIVER, and more made headlines from major cardiovascular meetings, including ACC.20/WCC Virtual. Additionally, ACC's new expert consensus decision pathway on novel therapies for cardiovascular risk reduction in patients with type 2 diabetes, as well as new ACC/American Heart Association (AHA) guidelines addressing hypertrophic cardiomyopathy and valvular heart disease were also released in 2020.

Other top articles include a *Cardiology* magazine cover story addressing implicit bias; a joint statement from the ACC, the Association of Black Cardiologists and the AHA addressing issues of racism and violence; and a landmark *JACC* state-of-the-art review looking at the global burden of cardiovascular disease over the last 30 years (read more on this in our cover story on page 20).

JACC and Family: Most Talked About Articles in 2020

Hundreds of articles are published every year across all eight – and soon to be nine – of the journals in the *JACC Family of Journals*.

The five most talked about articles from the *Journal of the American College of Cardiology (JACC)* on social media and other

media include three related to COVID-19, one on nutrition and one on the impact of training for marathon on reversing aortic stiffening.

Scan this QR code to read these articles today.

- 1. Saturated Fats and Health: A Reassessment and Proposal for Food-Based Recommendations: JACC State-of-the-Art Review
- 2. Training for a First-Time Marathon Reverses Age-Related Aortic Stiffening
- 3. Reduction in ST-Segment Elevation Cardiac Catheterization Laboratory Activations in the United States During COVID-19 Pandemic
- 4. Association of Treatment Dose Anticoagulation With In-Hospital Survival Among Hospitalized Patients With COVID-19
- 5. COVID-19 and Thrombotic or Thromboembolic Disease: Implications for Prevention, Antithrombotic Therapy, and Follow-Up: *JACC* State-of-the-Art Review

Visit JACC.org/MostTalkedAbout for a list linked to the top five most talked about articles from each of the JACC specialty journals: JACC: Clinical Electrophysiology; JACC: Heart Failure; JACC: Cardiovascular Imaging; JACC: Cardiovascular Interventions; JACC: Basic to Translational Science; JACC: Case Reports and JACC: CardioOncology.

Late-Mortality Signal Associated With Paclitaxel-Coated Devices: An Update

n December 2018, Katsanos, et al., surprised the vascular community in publishing a meta-analysis demonstrating a late mortality signal for patients treated with paclitaxel-coated devices (PCDs) relative to uncoated devices.¹ Specifically, they performed a meta-analysis of summary-level data from randomizedcontrolled trials (RCTs) that showed an increase in mortality at two and five years (68% and 93% increase in risk, respectively) in patients treated with PCDs relative to uncoated percutaneous transluminal angioplasty (PTA) and bare metal stenting (BMS) in the femoropopliteal artery segment.

This meta-analysis has several methodological flaws for which it has been criticized. For example, the individual RCTs included in the study were designed to evaluate short-term safety endpoints. Therefore, there was significant loss to follow-up after the specified short-term endpoints were met. This is evident in the meta-analysis as the one-year analysis included 28 trials and 4,432 patients, whereas the five-year analysis included only three trials and 863 patients. The patient populations in the individual RCTs were also heterogeneous in terms of their comorbidities and lesion characteristics as well as the endovascular devices used. Because individual-level data were not analyzed, these differences in patient populations were not accounted for and may have biased the results of the meta-analysis.

Despite its flaws, the consequences of the Katsanos meta-analysis were far-reaching. RCTs, including BASIL III and SWEDEPAD I and II, were stopped.² The U.S. Food and Drug Administration (FDA) recommended that health care providers restrict the use of PCDs to high-risk patient populations.³ Prior to the publication of the Katsanos meta-analysis, PCDs had emerged as the standard of care for patients undergoing endovascular revascularization because they increase primary patency rates and reduce targetlesion revascularization relative to PTA and BMS.⁴⁻⁶

The FDA convened a Medical Device Advisory Panel in June 2019 to investigate the possibility of a late mortality signal associated with PCDs. In preparation, the FDA had analyzed internal pivotal trial data of FDA-approved PCDs, which included several trials that had been analyzed in the Katsanos meta-analysis. In their analysis, the FDA identified a late mortality signal associated with PCDs. However, they felt that no overarching conclusion could be drawn as there was substantial residual missing data, small patient sample sizes, and no clear relationship between paclitaxel dose and mortality.⁷ The FDA also reviewed observational data from Medicare claims, Optum claims, and the Vascular Quality Initiative registry.8 These analyses did not identify an association between PCDs and mortality.

The FDA concluded from the advisory panel that there was a signal of harm present, but a causal relationship could not yet be established. The FDA requested more long-term data to evaluate the possibility of a late mortality signal. They allowed these devices to remain on the market, but published a revised FDA Letter to Health Care Providers that reinforced the recommendations that PCDs should be reserved for patients at the highest risk of restenosis and alternative treatment options should be considered.⁹

New Data, More Insights

Since the FDA advisory panel, several studies have evaluated the association of mortality with paclitaxel. These include large observational studies, longer-term follow-up data from RCTs, and a meta-analysis of clinical trials (**Table 1**).

There have been multiple additional real-world observational data published, all of which have not demonstrated an increase in mortality among patients treated with PCDs compared with those treated with uncoated devices. These include studies performed in the Medicare database,^{10,11} German BARMER insurance claims database,¹² data on the application of paclitaxel-based drug-eluting stents (DES)¹³ and a study in the Society for Vascular Surgery Vascular Quality Initiative registry.¹⁴

The ongoing Safety Assessment of Femoropopliteal Endovascular treatment with Paclitaxel-coated Devices (SAFE-PAD) study (*clinical-trials.gov* NCT04496544)¹⁵ includes prespecified sensitivity analyses to assess the influence of unmeasured confounding as well as subgroup analyses to examine low-risk populations, inpatients vs. outpatients, critical limb ischemia (CLI), and device type among Medicare patients. The first report from this study has reaffirmed findings from previous Medicare analyses, with no evidence of long-term harm associated with these devices.

Rocha-Singh, et al., performed a meta-analysis of individual patient-level data from eight RCTs.¹⁶ As part of this analysis, the investigators obtained follow-up data that reduced the loss to follow-up present in the original studies. With 27% and 25% loss to follow-up in treatment and control arms, respectively, they reported a mortality hazard ratio associated with PCDs of 1.38 (95% confidence interval [CI], 1.06-1.80). When loss to follow-up was reduced to 10% and 9% for treatment and control arms, respectively, the hazard ratio decreased to 1.27 (95% CI, 1.03-1.58). Hence, although the authors demonstrate a relationship between treatment with PCDs and mortality remained, they showed this association was attenuated as loss to follow-up was reduced. This suggests that patients missing long-term follow-up may not have been lost at random. Notably, there was no evidence of a dose-response relationship between paclitaxel and mortality.

Long-term follow-up from industry-sponsored RCTs also have been reassuring. This includes five-year data from IN.PACT SFA and IN.PACT Japan,¹⁷ four-year results from the Illumenate Pivotal trial,¹⁸ and five-year follow-up data from the LEVANT trials.¹⁹ A five-year as-treated analysis from the Zilver PTX trial comparing 336 patients who were treated with DES to 143 patients treated with PTA showed no difference in mortality between the two groups.²⁰ For all these analyses, causes of death were analyzed between each treatment arm and no significant differences were identified.

An unplanned interim analysis from SWEDEPAD was recently published. The multicenter, randomized trial assigned 2,289 patients to either a drug-coated device or uncoated device and followed them a mean 2.49 years. No difference was seen in all-cause mortality between patients treated with PCDs (25.5%) vs. uncoated devices (24.6%) (HR, 1.06; 95% CI, 0.92-1.22). Stratification by CLI and intermittent claudication showed no difference in mortality between patients with CLI treated with PCDs vs. uncoated devices (HR, 1.04; 95% CI, 0.90-1.21). Similarly, no difference was seen in mortality in patients with intermittent claudication treated with PCDs vs. uncoated devices (HR, 1.18; 95% CI, 0.72-1.93).²⁵

Hess, et al., performed a subgroup analysis of patients who underwent endovascular revascularization with PCDs or non-PCDs in patients from the VOYAGER PAD trial.²¹ The VOYAGER PAD trial was a double-blind, placebo-controlled trial of patients with PAD undergoing lower-extremity revascularization who were randomized post treatment to receive rivaroxaban 2.5 mg bid or placebo on a background of aspirin 100 mg daily.²² Of the 4,379 patients in the trial who underwent endovascular revascularization, 31% (1,358) were treated with a PCD. Patients were followed for a median of 31 months and vital status was ascertained for 99.6% of patients. After adjusting for confounders using inverse probability of treatment weighting, the investigators found no association between treatment with PCDs and mortality.

The Way Ahead?

In summary, since the publication of the Katsanos meta-analysis, there have been ample data published or presented from large, observational datasets, subgroup analyses from RCTs, and long-term follow-up from the pivotal PCD RCTs. None of these studies has been able to replicate an association between PCDs and mortality. Furthermore, several studies have now analyzed causes of death in patients who were treated with PCDs vs. non-PCDs and have not found significant differences between groups. Lastly, no clear mechanism relating paclitaxel to death has been described and a dose-response relationship between paclitaxel and mortality has not been established. As this controversy is now approaching two years, the vascular community awaits next steps from the FDA and other regulatory bodies in determining the long-term future of PCDs.

Secemsky MD**, **MSc**, **FACC**, director of Vascular Intervention in the CardioVascular Institute at BIDMC, and assistant professor at Harvard Medical School, and the Smith Center for Outcomes Research in Cardiology at BIDMC.

Innovation at ACC

Reimagining the Heart Health Journey

ver the past year, the COVID-19 pandemic has further highlighted the challenges facing cardiovascular patients seeking to navigate the complex health care landscape. With no clear compass to guide their health journey, many patients are left trying to make sense of symptoms on their own and experiencing delays in diagnosis and/or treatment due to a health system that has reached critical mass.

How can we change this trajectory and make patients the architect of their own health care journey? One solution is a technology infrastructure that puts patients first and enhances their engagement with their clinicians and the health care system outside of clinic-based settings. Enter Evidation Health.

As part of its strategic Innovation efforts, the ACC is joining forces with Evidation Health to co-develop and launch Achievement for Heart Health, an individualized, curated health program. Co-developed by a team of experts from the ACC, Achievement for Hearth Health is designed to empower individuals to better manage their heart health from anywhere.

Through the program, which will initially focus on heart failure, individuals will be able to continuously monitor and learn from data relevant to their cardiovascular health from the comfort of their home. Individuals can share activity, sleep, blood pressure, and symptom information, including permissioned app and wearable data (**Figure 1**). Participants will also receive personalized, evidence-based educational content on topics like heart medications, nutrition, and stress management from ACC's CardioSmart program.

"The Achievement for Heart Health program will help the ACC and our research partners better understand the complex, individualized patient journey of those with heart failure, with a goal of improving how patients live with and manage one of the most common cardiovascular conditions affecting Americans today," said ACC Chief Innovation and Science and Quality Officer John S. Rumsfeld, MD, PhD, FACC. "The combination of Evidation's platform and ACC's clinical and scientific expertise will enable groundbreaking opportunities to transform cardiovascular care and improve heart health and outcomes."

The new program will be built on Evidation's Achievement platform and will be open to collaborators following Evidation's consent-per-use model, where participants provide consent for each program in which they participate and receive compensation for their contribution to research. The platform is the largest and most demographically and geographically diverse connected cohort in the U.S., representing

h

Achievemen

50 states and nine of every 10 ZIP codes nationwide. Learnings from this program will be used to iteratively inform and refine the patient experience, providing more tailored insight and support to navigate the health care system.

> "We are proud to collaborate with the ACC, which is already leading the digital transformation of cardiovascular care delivery, to broadly expand individuals' access to their world class expertise, research, and educational

Figure 1

Interested in Getting Involved?

resources," said **Deborah Kilpatrick, PhD,** Co-CEO of Evidation. "Together with the ACC, we look forward to collaborating with researchers

patients in their everyday life."

and sponsors who are committed to developing

products and services that are directly informed by

The ACC and Evidation invite collaborators who share an interest in developing new ways to empower individuals to better manage their heart health to reach out at partners@evidation.com.

Implementing the New ACC/AHA Guideline on Valvular Heart Disease

n updated Guideline for the Management of Patients With Valvular Heart Disease (VHD) includes expanded treatment options, recommends fewer invasive interventions, when possible, and stresses the importance of patient involvement in treatment considerations.

The new guideline from the ACC and American Heart Association (AHA), and published in the Journal of the American College of Cardiology, replaces the 2014 guideline and a focused update from 2017, and includes an extensive review of available data through March 1, 2020.

Highlighted in the guideline is expansion of indications for transcatheter aortic valve implantation (TAVI) as a result of multiple randomized trials of TAVI vs. surgical aortic valve replacement. According to the guideline, "the choice of type of intervention for a patient with severe aortic stenosis should be a shared decisionmaking process that considers the lifetime risks and benefits associated with type of valve (mechanical vs. bioprosthetic) and type of approach (transcatheter vs. surgical)."

In addition, the evidence for non-vitamin K oral anticoagulants (NOACs) has improved since the last guideline was published, and the new guideline includes a class 1 level A recommendation that states: "For patients with AFib and native valve heart disease (except rheumatic mitral stenosis) or who received a bioprosthetic valve >3 months ago, a NOAC is an effective alternative to [vitamin K antagonist] VKA anticoagulation and should be administered on the basis of the patient's CHA₂DS₂-VASc score."

Other recommendations address the optimal timing of intervention for severe aortic stenosis, which depends on the severity of the valve condition, as well as the safety and long-term effectiveness of treatment options. The guideline authors note that the recommended timing of interventions will shift to earlier in the disease course for some patients as ongoing clinical research data evolves. Additionally, the guideline recommends that patients with severe VHD and who are being considered for valve repair or replacement should be evaluated by a specialized team working with a primary or comprehensive valve center.

Integration of this expanded evidence base, in conjunction with expert clinical experience, will furnish both providers and patients with the guidance needed to ensure optimal outcomes for patients with heart valve conditions. // Catherine Otto, MD, FACC

Shared decision-making and the use of less-invasive treatment options are other important aspects of the new guideline. "Clinical studies have demonstrated the safety and effectiveness of new, less-invasive approaches for treatment of heart valve dysfunction," says Catherine Otto, MD, FACC, co-chair of the guideline writing committee. "Integration of this expanded evidence base, in conjunction with expert clinical experience, will furnish both providers and patients with the guidance needed to ensure optimal outcomes for

patients with heart valve conditions."

Looking ahead, the guideline committee recommends more disease-specific studies and patient-centered trials that focus on each stage of the disease process. "While this guideline focuses on patients with end-stage heart valve disease, future research will also lead to treatments to prevent heart valve disease or earlier interventions to slow its progression," explains Otto.

"There is a knowledge explosion in medicine today, which can overwhelm the clinician," says Rick A. Nishimura, MD, MACC, co-chair of the writing

> committee. "This is particularly true in the area of VHD, in which multiple investigational trials are being rapidly performed and released, so that it becomes extremely difficult for an individual clinician to keep up with optimal treatments for each specific patient. The

Valvular Heart Disease Guideline brings together experts in the field who review all the data and arrive at a consensus opinion for best treatment, outlined in the Class Recommendations."

The guideline was developed in collaboration with and endorsed by the American Association for Thoracic Surgery, the American Society of Echocardiography, the Society for Cardiovascular Angiography and Interventions, the Society of Cardiovascular Anesthesiologists and the Society of Thoracic Surgeons.

Putting the VHD Guideline Into Practice

Involve your patients in their VHD care using CardioSmart shared decision-making tools and focused infographics on VHD and TAVR. Learn more at CardioSmart.org.

KEY PERSPECTIVES: VHD Guideline Key Points to Remember

David S. Bach, MD, FACC, highlights general considerations for patients with aortic stenosis (AS), aortic regurgitation (AR) or bucuspid aortic valve (BAV).

The guideline continues to recommend the use of disease stages among patients with VHD: Stage A (at risk), Stage B (progressive), Stage C (asymptomatic severe; with ventricular compensation [Stage C1] or with ventricular decompensation [Stage C2]), and Stage D (symptomatic severe). Disease stages should be assigned based on valve anatomy, the severity of valve dysfunction, the ventricular and pulmonary circulation response to valve dysfunction, and symptoms.

Among patients with atrial fibrillation (AFib) and native heart valve disease other than rheumatic mitral stenosis, or in patients with AFib and a bioprosthesis >3 months after valve replacement, a NOAC is an effective alternative to anticoagulation with a VKA; among these patients, either a NOAC or VKA should be used based on the CHA₂DS₂-VASc score. Anticoagulation with a VKA should be used in patients with AFib and rheumatic mitral stenosis. A NOAC should not be used in patients with a mechanical prosthesis without or with AFib.

All patients with severe VHD being considered for intervention should be evaluated by a Multidisciplinary Heart Valve Team. Consultation with or referral to a Primary Valve Center or a Comprehensive Valve Center is reasonable for the discussion of treatment options in the setting of asymptomatic patients with severe VHD, patients who might benefit from valve repair rather than valve replacement, and patients with multiple comorbidities.

In patients with severe symptomatic (Stage D) AS, the disease is subcategorized based on the gradient, flow and left ventricular ejection fraction (LVEF). Stage D1 reflects patients with high-gradient symptomatic AS ($V_{max} \ge 4.0$ m/s, mean gradient ≥ 40 mm Hg, aortic valve area [AVA] ≤ 1.0 cm²); Stage D2 reflects low-flow, low-gradient severe AS with reduced LVEF (AVA ≤ 1.0 cm2, $V_{max} < 4.0$ m/s or mean gradient < 40 mm Hg, LVEF < 50%); and Stage D3 reflects low-flow, low-flow, low-gradient severe AS with normal LVEF ("paradoxical low-flow severe AS"; LVEF $\ge 50\%$, stroke volume index < 35 ml/m²).

Intervention for severe AS predominantly is based on the presence of symptoms or LV systolic dysfunction (Class 1); or in asymptomatic patients at low surgical risk with decreasing exercise tolerance or exerciseassociated decrease ≥ 10 mm Hg in systolic blood pressure, very severe AS ($V_{max} \geq 5.0$ m/s), serum B-type natriuretic peptide (BNP) >3 times normal, or progression of $V_{max} \geq 0.3$ m/s per year (Class 2a). In addition, intervention can be considered among asymptomatic patients with severe high-gradient AS and a progressive decrease in LVEF to <60% on \geq 3 serial imaging studies (Class IIb).

Among patients in whom a bioprosthesis is appropriate, decisions between surgical aortic valve replacement (SAVR) and transcatheter aortic valve implantation (TAVI) should include the presence of symptoms, patient age and anticipated life expectancy, the indication for intervention, predicted surgical risk, and anatomy or other factors referable to transfemoral (TF) TAVI feasibility (all Class 1):

- SAVR is preferred among patients <65 years of age or with life expectancy >20 years.
- SAVR is preferred if vascular anatomy or other factors preclude TF TAVI.
- SAVR is preferred among asymptomatic patients with a Class IIa indication for intervention, such as an abnormal exercise test, very severe AS, rapid progression, or elevated BNP.
- If feasible, TF TAVI is preferred among patients >80 years of age or with life expectancy <10 years.
- SAVR or TF TAVI is recommended after shared-decision making among symptomatic patients ages 65-80 years with no contraindication to TF TAVI.
- TAVI is preferred among symptomatic patients of any age with high or prohibitive surgical risk, if predicted survival after intervention is >12 months with an acceptable quality of life.
- After shared-decision making, palliative care is recommended among symptomatic patients with predicted post-TAVI survival <12 months or for whom minimal improvement in quality of life is expected.

Among patients with asymptomatic severe (Stage C) AR, the disease is subcategorized based on LVEF and LV end-systolic diameter (LVESD). Stage C1 reflects normal LVEF (\geq 55%; previously \geq 50% in the 2014 AHA/ACC guidelines) and mild to moderate LV dilation (LVESD <50 mm). Stage C2 reflects abnormal LV systolic function (LVEF <55%; previously <50%) or severe LV dilation (LVESD 50 mm or indexed LVESD >25 mm/m2; unchanged from previous).

Intervention for severe AR is based on the presence of symptoms or LV systolic dysfunction (LVEF ≤55%; both Class 1); or the presence of severe LV dilation (LVESD >50 mm or indexed LVESD >25 mm/m²; Class IIa).

Among patients with BAV, transthoracic echocardiography is recommended to assess valve morphology, assess AS and AR, assess the aortic root and ascending aorta, and evaluate for the presence of aortic coarctation. If the aortic sinuses, sinotubular junction and ascending aorta cannot be accurately or fully assessed on echocardiography, then cardiac magnetic resonance angiography or computed tomography angiography is indicated. Lifelong serial imaging is indicated if the aorta diameter is ≥4.0 cm.

Among patients with BAV, indications for replacement of the aorta remain similar to previous: aortic diameter >5.5 cm (Class I), aortic diameter 5.0-5.5 cm plus an additional risk factor for dissection (family history of dissection, aortic growth >0.5 cm per year, aortic coarctation; Class IIa), or aortic diameter ≥4.5 cm with an indication for SAVR (Class IIa).

New Year, New Opportunities For Cardiovascular Care Transformation

Embracing the Pandemic as a Disruptor and Innovation Catalyst

he world has experienced a year unlike any other in this generation, putting 2020 in the history books as the year of COVID. As 2021 begins, it's important to take time to consider the long-term impacts from the pandemic on the health care industry and patient care. Although history books will focus on the *pandemic* of 2020, the health care industry could, and should, focus on the *disruptor* of 2020.

A disruptor is defined as something that interrupts an event, activity or process by causing a disturbance or problem. A disruptor can also be a force for good when it causes radical change in an existing industry or market by means of innovation, a concept often highlighted in the business industry but rarely used in conjunction with changes in the health care industry.

The current trajectory of health care in the U.S. is not economically sustainable and not maximally effective. Accordingly, health care leaders and society at large agree change is needed. As opposed to small, incremental improvements, the health care industry needs a significant disruption. Viewed through the lens of disruption, innovation and care transformation, there is no opportunity for change like the present.

The pandemic has created economic instability for most health care organizations and providers. Other effects include less than desired patient outcomes from poor access; missed care opportunities; worsening of existing health disparities due to lack of resources and technology needed to seek health care; and a burned out health care workforce. While these challenges aren't new, they've been amplified by the pandemic and there's an increased urgency to implement solutions.

Historical events, such as the 1918 flu pandemic, have provided valuable insights into the effects of a public health emergency, both short- and long-term. From a health care delivery standpoint, many governments embraced new concepts of preventive medicine and socialized medicine after the 1918 flu pandemic. The U.S. also adopted the employer-based insurance plans that expanded access to health care for the general population.¹ Fast forward to the 2020 pandemic and there are many opportunities for innovation in cardiovascular care with hints at transformation, but no clear path to achieving true transformation. If the 2020 pandemic is not seized as a disruptor and catalyst for innovation and care transformation, it will be a missed opportunity.

Disruption creates a need for action. For some, the action will be to look inward and make changes to do more with less. Others will look externally to see how the disruption has changed the industry and patient and provider needs, and look to innovate and transform to better meet those needs. A review of this concept in the business industry suggests looking inward often leads to demise, while looking outward can lead to expansion into new services and markets, creating a trajectory otherwise unforeseen.²

Applying Disruption, Innovation to Cardiovascular Care

There is a significant body of literature about leadership in health care. Effective organizations bring the right people to the table with requisite skills in both management and leadership.^{3,4}

Cardiovascular programs need an effective leadership and management structure to provide vision and foster an environment supportive of innovation and transformation. Applied to surviving during a time of disruption, management will tend to concentrate on preserving and improving the status quo, while leadership is about challenging the status quo and creating something different and more effective.⁵

Where does a program start? Here are three types of innovation described by Regina Herzlinger, Harvard Business school faculty,⁶ viewed through the lens of the COVID pandemic.

1 Change the Way Consumers Buy and Use Health Care Early in the pandemic, MedAxiom described the rapid transition to virtual care through telehealth

services in its "Survey Report: Impact of COVID-19

on Cardiovascular Organizations," published in April 2020. The survey found most programs transitioned to a virtual delivery model in less than two weeks and changes in reimbursement and regulations that supported the transition closely followed.

Numerous learnings stemmed from the transition to virtual care delivery. The transition highlighted the capabilities and ability to do this work effectively while putting a spotlight on disparities in access to health care. Patients without access to technology had an even harder time receiving needed care.

Further, the early pandemic forced a shift from preventive, routine care to urgent-only care. Many stories have been shared about patients who waited too long to seek care or missed routine evaluations only to present with acute needs. A shift in the health care delivery model needs to recognize these disparities and assure access to routine, preventive care, as well as urgent needs. Virtual care worked, and needs to stay, but must evolve. A digital transformation must complement face-to-face care such that virtual care be embedded when and where it is most effective for communication, care coordination and care delivery.

2Use Technology to Develop New Products and Treatments

Device therapies, pharmacologic therapies and procedural therapies have all progressed in recent years. Innovations are allowing clinicians to make earlier diagnoses and providing tools for effective primary and secondary prevention. In coronary artery disease, noninvasive imaging technologies are emerging that provide both anatomic and functional data to better define risk and can guide management strategies. The anticipated result is a shift toward health maintenance

with reduced need for, and more effective use of, invasive treatment options. A recent article in the *Journal of the American College of Cardiology* by Ferraro, et al, provides a disruptive example using the evaluation and treatment of patients with stable angina with a CT-guided algorithm.⁷

There are many other examples that will have an impact on workforce needs, skillsets, operational processes and changes in both provider and patient expectations. Team-based, multidisciplinary care will promote effective and efficient care. The pandemic has caused programs to redeploy providers, develop new care pathways and redefine relationships with hospitalists, emergency departments, intensivists and with each other. This redeployment of providers, which utilizes skillsets in unique ways, was an innovation and proved the cardiovascular industry's ability to adapt. Barriers that were economic and related to "turf" were broken down with ease and grace. However, solutions to support long-term transitions are required and reimbursement changes and physician compensation models must adjust to support/encourage team-based care delivery. The work must happen at a pace that will support innovation and a true transformation of care.

3 Generate New Business Models that May Involve Horizontal or Vertical Integration of Separate Health Care Organizations or Activities The traditional fee-for-service model is at a tipping point. The pandemic has shown that a reactive care delivery model in a fee-for-service funded environment is ineffective. Limitations to elective procedures, ambulatory care services and overall reluctance to seek health care has created an economic perfect storm for health care organizations. In addition, nonacute services that utilize acute care hospitals as their site of service came to a halt. This created both economic struggles and more importantly missed care opportunities.

Viewed through the lens of disruption, **innovation and care transformation**, there is no opportunity for change like the present.

The cardiovascular industry recognizes the opportunity to transition many services to ambulatory surgical centers (ASCs) and office/outpatient departments. The pandemic has highlighted that having nonacute care sites of service is important. An example of a recent delivery innovation in the cardiovascular space is the transition of PCI to an ASC. A position statement from SCAI in May 2020 stated: "the ability to perform PCI in an ASC has been made possible" and is happening effectively when structured appropriately.⁸ However, full adoption will require multiple changes including health policy, economic alignment, facility planning, integration models and operational structures.

Looking Forward

As tragic as the last year has been, there is an opportunity to use the disruption to create positive, lasting change. Dyad leadership, a vision for innovation and embracing lessons learned will allow true cardiovascular care transformation. Vision and leadership are the key ingredients in the innovations that will transform care. The ACC and MedAxiom have a joint mission: "To transform cardiovascular care and improve heart health." We are in the business of care transformation and will work tirelessly to lead members with vision, education, organizational resources and advocacy. Let's transform cardiovascular care, together.

Heart of Health Policy

ACC Advocacy: Top 10 Highlights of 2020

he COVID-19 pandemic, while testing the limits of resilience and requiring unprecedented flexibility and creativity, also underscored the importance and value of advocacy. From the very onset of the pandemic, ACC Advocacy leaders and staff proactively sprang into action to deliver solutions aimed at helping cardiovascular patients, clinicians and institutions navigate the many challenges posed by the virus.

Moreover, other health policy activities didn't stop for the pandemic and members and staff worked hard to deliver on the College's key Advocacy priorities related to reducing administrative burden and promoting clinician well-being; leading the transition to models that strengthen value and patient outcomes; promoting practice stability and patient access to affordable care; optimizing care, outcomes and health; and advancing member engagement and leadership.

The top 10 Advocacy highlights from 2020 help to illustrate the many ways ACC Advocacy is working to deliver on the College's Mission and Vision.

Cardiologist Opportunity in the Beautiful Berkshires ~ Western MA

Berkshire Health Systems Opportunity

- BC/BE General //Cardiologist
 1-5 Call rotation
- 1-5 Call rotation
- COCATS level 2 or greater in Echocardiography, ECG, Nuclear Stress Tests, Holter and Event monitors, is required
- Training in advance imaging including CT, MR and PET is preferred
- Diagnostic Catheterization Lab and full service Electrophysiology Lab on site
- Competitive compensation and benefits package, including productivity option and relocation
 We understand the importance of balancing work with a healthy personal lifestyle.
 Berkshires, a 4-season resort community, with ample cultural opportunities
- Derksnires, a 4-season resort community, with ample
 World renowned music, art, theater, and museums
- Your renowned music, and museums
 Year round recreational activities from skiing to kavaking
- Excellent public and private schools make this an ideal family location,
- Just 2 ½ hours from both Boston and New York City.

Berkshire Medical Center, BHS's 302-bed community teaching hospital and Trauma Center, is a major teaching affiliate of the University of Massachusetts Medical School, and a Top 100 Hospital. With the latest technology and a system-wide electronic health record, BHS is the region's leading provider of comprehensive healthcare services.

This is a great opportunity to practice in a beautiful and culturally rich area while being affiliated with a health system with award winning programs, nationally recognized physicians, and world class technology.

COVID-19 FUNDING

Thanks to a record-breaking 12,000 grassroots messages and persistent lobbying efforts, Congress passed four COVID-19 legislative packages over the course of 2020, bolstering supply of personal protective equipment, ventilators, and diagnostic testing while also creating the Provider Relief Fund and the Paycheck Protection Program to help practices remain financially stable.

TELEHEALTH FLEXIBILITIES

In response to feedback from the ACC and others, Congress directed the Centers for Medicare and Medicaid Services (CMS) to broaden access to telehealth during the COVID-19 public health emergency (PHE), removing obstacles such as originating site and platform requirements, and ultimately also allowing for cardiac and pulmonary rehabilitation services.

TELEHEALTH REIMBURSEMENT

Thanks to ACC Advocacy efforts underscoring the value of telehealth, CMS, along with numerous commercial payers, agreed to pay the same rate for many telehealth services as in-person services. Also of note, discussions with policymakers convinced public and several private payers to recognize patients' need for audio-only telehealth services with payment at similar rates to audio-visual telehealth. Visit ACC's COVID-19 Hub (*ACC.org/COVID19*) for telehealth resources from both the College and MedAxiom.

BUDGET NEUTRALITY

Responding to the concerns of ACC and others, Congress added funds to the 2021 Medicare Physician Fee Schedule that mitigate statutorily required budget neutrality payment reductions to balance increased payment for evaluation and management (E/M) services.

LEGISLATIVE CONFERENCE

The ACC's 2020 Legislative Conference was the largest to date, with 614 participants spanning the entire cardiovascular care team. Virtual educational sessions helped to educate clinicians about the most pressing health policy issues before Congress and a total of 327 virtual meetings were held with members of Congress and/or their staff. **Scan the QR code to learn more and save the date for this year's conference.**

VAD COVERAGE

At the urging of ACC, CMS eliminated the outdated intent to treat coverage indications for Ventricular Assist Device (VAD) candidates. **Scan the QR code to read more.**

VALUE-BASED CARE

The ACC convened seven national health plans and Medicare leaders through its Value-Based Care in Cardiology Forum in December. The innovative forum focused on developing new payment models for treating recently diagnosed atrial fibrillation patients. **Scan the QR code for more on value-based care in ACC's Alternative Payment Model hub.**

COVID-19 STATE ADVOCACY

Efforts by ACC's State Advocacy Team, working closely with ACC's State Chapters, were influential in helping to expand telehealth access, implement health care worker liability protections, and retain appropriate patient access to cardiovascular care as part of numerous state PHE responses.

STATE ADVOCACY

ACC State Chapters and ACC grassroots members were successful on several state legislative fronts in 2020, including continued adoption of Tobacco 21 legislation, as well as prior authorization reform.

HeartPAC

Cardiovascular disease doesn't discriminate based on political party. As such, the ACC has a long history of working with members of Congress on both sides of the aisle to advance health policy solutions that are best for cardiovascular patients and clinicians. During the 2020 Election Cycle, ACC's HeartPAC distributed \$749,500 to members of Congress, 95% of whom were victorious in their races. Learn more at *HeartPAC.org*.

St. Luke's University Health Network, the region's largest, most established health system, a major teaching hospital, and one of the nation's 100 Top Hospitals is seeking a BC/BE Non-Invasive Cardiologist to join our growing Network and dedicated team of physicians and advanced practitioners providing excellent care at St. Luke's University Health Network. This opportunity will reside at our St. Luke's Easton Campus, a community hospital located in Easton, PA that provides an array of consultative cardiology and non-invasive cardiac services.

St. Luke's Easton Campus is the most recent hospital to join St. Luke's University Health Network. At St. Luke's Easton Campus, we have a full-service Emergency Department with access to deep expertise from a broad array of specialists in the St. Luke's Network. Our patients benefit from nationally recognized high-quality care with a great team of clinical and support staff all working together.

Currently, this opportunity will focus primarily on providing unmatched care including detection and treatment of heart disease. We are seeking dynamic candidates who are interested in being a part of our continued growth and development at our newest hospital.

The collective SLUHN Cardiology team includes 45+ cardiologists supported by 25 advanced practitioners. Critically, we have the full support of our health network to provide the region's 2.6 million people with access to the most sophisticated cardiology care available. Our cardiovascular practice includes all aspects of cardiology and we currently have a full Cardiology Fellowship and free-standing medical school.

In joining St. Luke's University Health Network you'll enjoy:

- Team-based care with well-educated, dedicated support staff
- A culture in which innovation is highly valued
- Exceptional compensation package and relocation reimbursement
- Starting bonus
- Rich benefits package, including malpractice, health and dental insurance, and CME allowance
- Teaching, research, quality improvement and strategic development opportunities
- A physician orientated unique culture
- A reasonable call schedule, enjoy a work/life balance

About St. Luke's University Health Network

Founded in 1872, <u>St. Luke's University Health Network</u> (SLUHN) is a fully integrated, regional, non-profit network of more than 16,000 employees providing services at 12 hospitals and 300+ outpatient sites. With annual net revenue greater than \$2 billion, the Network's service area includes 11 counties: Lehigh, Northampton, Berks, Bucks, Carbon, Montgomery, Monroe, Schuylkill and Luzerne counties in Pennsylvania and Warren and Hunterdon counties in New Jersey. Dedicated to advancing medical education, St. Luke's is the preeminent teaching hospital in central-eastern Pennsylvania. For more information about St. Luke's, please visit <u>www.slhn.org</u> and for information about the Lehigh Valley, please visit <u>www. discoverlehighvalley.com</u>. *We do not sponsor visas

If you are interested in learning more about this opportunity, please contact: Christine Figler, <u>Christine.Figler@sluhn.org</u>

he ACC strives to lead in diversity, equity and inclusion and seeks to foster a supportive and inclusive culture within our organization and in the cardiovascular community. To help all leaders prepare for facilitated conversations with peers or groups about racism, race and ethnicity in professional settings, the Diversity and Inclusion Task Force developed a discussion guide with techniques that can be used during discussions to foster an open dialogue and suggested steps to take following a discussion to continue the dialogue.

DO YOUR RESEARCH.

• It is critical for the leader to understand the privilege that shapes their world view and to educate themselves about what they need to learn and/or unlearn to be an advocate and ally.

BE PREPARED TO TALK ABOUT SHARED VALUES OF JUSTICE, OPPORTUNITY FOR ALL AND FAIRNESS/HEALTH EQUITY, BUT ALSO BE PREPARED TO HEAR COUNTER-NARRATIVES.

• Articulate the shared values of justice, opportunity for all, fairness and health equity at the start of the conversation. Explain how discrimination and unequal opportunity harm people and how systemic biases affect all of us from achieving our full potential.

APPROACH THE CONVERSATION WITH RESPECT AND EMPATHY.

• Respect the struggles individuals may have gone through to get where they are today, their narratives, and the pain and oppression they have experienced. Coming from a respectful place and letting each person know you are there to actively listen, learn and understand can help navigate challenging and difficult conversations.

APPROACH THE CONVERSATION WITH AN OPEN MIND - GET RID OF PRECONCEPTIONS.

• Acknowledge what you don't know and the openness to learn. Express that everyone is here to learn more about different perspectives. Be prepared to be the role model for the conversation via your actions and set the tone.

CREATE THE RIGHT ENVIRONMENT.

 Hold the conversation in a confidential space that allows individuals to feel comfortable discussing sensitive/difficult topics. Set ground rules for conversation, letting individuals know they can feel safe to speak without judgement.

Scan the QR code for the complete discussion guide for more best practices on what leaders can do to prepare for a

discussion on racism, race and ethnicity in the professional setting.

RACISM, RACE AND ETHNICI

WHAT YOU SHOULD DO OR SA DURING THE CONVERSATION

Scan this QR code for ACC's Anti-Racism Resource Center.
